To His Excellency

Johann Count Zichy of Zich and Vásánkeő,

Imperial and Royal Chamberlain, Member of the Privy Council, Royal Hungarian  
Minister of Education,

this book is dedicated with deep respect and gratitude

by the Author.

# Introduction.

---

I have gladly acceded to the request of my colleague Prof. Onodi that I should write an introduction to his book on the Anatomy and Topography of the Accessory Air Sinuses of the Nose in Childhood. In view of the fact that these pneumatic cavities of the skull are still so little understood, especially in their physiological bearings, every fresh contribution to their exact study is of value; but especial importance attaches to a research on their development, such as is given in this work. For our best method of elucidating the problems of Normal and Comparative Anatomy is always afforded by an investigation of the mode of development of the organs in question.

The object of this work has been to study the development of the air sinuses from their first appearance until after the beginning of puberty. To this end a number of sections have been cut through the skulls of infants and children of different ages. The sections have been laid in the three principal planes of the body and appear to me to have been well chosen. Since accurate measurements are given in every instance, a good idea is afforded of the gradual development of the frontal and sphenoidal sinuses, the anterior and posterior ethmoidal cells and the maxillary antrum. One of the necessary foundations has thus been laid upon which must rest any subsequent investigation of the form, relations and functions of these important air cavities.

From a practical point of view, the illustrations and measurements given in this book appear to me to have considerable importance particularly for the diagnosis and operative treatment of the accessory sinuses in children, since they enable the surgeon to select and to follow up the best route of access to such cavities. In view of the great difficulty of diagnosing and operating for diseases of the sinuses in children, every contribution should be welcomed which helps to overcome these obstacles.

**Waldeyer.**

# Preface.

---

In the investigations which I have hitherto undertaken on the accessory air sinuses of the nose, I have been keenly alive to the incompleteness of our knowledge of these sinuses in the child. So far as I know, the text-books contain only scanty and somewhat vague references to this subject. It has been my endeavour to supply this want, and at the same time to make the most complete use possible of the material at my disposal. My specimens have been cut with a fret-saw in coronal, longitudinal, and horizontal planes, and are reproduced photographically in their natural size. The series has been completed by the inclusion of skiagrams prepared from different skulls. The resulting atlas contains 102 plates, shewing, in various planes, the situation and size of the different sinuses, as well as their relations with one another and with the nasal cavity. The illustrations afford a clear view of the morphological aspect of the air sinuses in children, whilst the information given as to the natural size and measurements of these cavities should prove particularly instructive and useful in operative surgery. Of late years the number of operations on the diseased sinuses of children has shewn a considerable increase, such operations having been performed in children of  $1\frac{1}{3}$ ,  $2\frac{1}{3}$ , 3,  $3\frac{1}{2}$ , 4, 5, 6,  $6\frac{1}{4}$ ,  $6\frac{1}{2}$ , 7, 9, 10, 12, etc., years. The material from which the illustrations of this atlas have been prepared, was obtained from foetuses of  $6\frac{1}{2}$  and 8 months, from new-born infants, and from a number of children, aged, respectively, 1, 2, 4,  $4\frac{1}{4}$ ,  $4\frac{1}{2}$ , 5,  $5\frac{1}{2}$ ,  $6\frac{1}{2}$ , 7, 8, 11, 12, 14, and 15 months,  $1\frac{1}{2}$ , 2, 3,  $3\frac{1}{2}$ , 6,  $7\frac{1}{2}$ ,  $8\frac{1}{2}$ , 9, 11, 12, 13,  $13\frac{1}{2}$ , 14, 15, 18 and 19 years. Some of the skulls shewed variations in the size and general arrangement of the sinuses, such morphological differences being the forerunners of those variations which are so frequently observed in the sinuses of the adult.

I venture to hope that this volume which I am now publishing will successfully supply an often-felt want, and that it will be of general use to every physician who wishes to extend his knowledge and to obtain an exact insight into the complicated structure of the sinuses of the child. I trust that my atlas will be a welcome addition to the libraries of my brother specialists as well as of surgeons, specialists for diseases of children, oculists and otologists. May it thus prove a stimulus for the further and more detailed investigation of the pathology and treatment of the diseases of the sinuses in children.

I welcome the opportunity of expressing my most cordial thanks to the Hungarian Academy of Sciences for its valuable assistance, and further to Hofrat Professor Dr. *M. von Lenhossék* and to Prosector Dr. *L. Nagy* for their kindness in giving me the use of their material. I am indebted to my translators for the labour which they have devoted to their work. The French translation was kindly undertaken by Dr. *Lautmann* in Paris, the English translation by Dr. *Prausnitz* in Breslau. My special thanks are due to my publisher for the care which he has bestowed upon the arrangement and appearance of the book.

Budapest, 15th December 1910.

Ónodi.

Synopsis of Results.

## Synopsis of Results.

### I.

The condition of the accessory sinuses of the nose in childhood has not hitherto been investigated systematically. Valuable data, it is true, are already known as to their early development in the foetus. But vague, general and often contradictory are the scanty items of information supplied by anatomical and rhinological text-books as to the condition of the sinuses in children. It has been the object of our investigations to fill this gap and to supplement the information both as regards purely anatomical data, and by reproducing the illustrations in their natural size and selecting them with a view to their use in operations. We will begin by giving a *résumé* of the anatomical data, and will afterwards consider the practical importance of these results in the treatment of diseases of the accessory sinuses in childhood.

#### 1. The Frontal Sinus.

With regard to the development of the frontal sinus, I have taken account of the investigations of Steiner<sup>1)</sup>, Merkel<sup>2)</sup>, Killian<sup>3)</sup>, Zuckerkandl<sup>4)</sup> and Boege<sup>5)</sup> in my monograph dealing with the frontal sinus (Vienna 1909). I do not propose to describe in detail the structural conditions of the foetal germs of these sinuses. I would, however, mention that the frontal depression called "frontal recess" by Killian, has been described by Mihálikovics<sup>6)</sup> under the name of "recess of the middle meatus". From this recess the frontal sinus arises directly, although according to Killian it may also develop indirectly from an ethmoidal cell, the so-called "frontal cell". The following data will serve to shew the views of different authors as to the development of the frontal sinus in childhood. Steiner described it as developing between the first and second year, and attaining the size of a pea about the sixth or seventh year. According to Aeby<sup>7)</sup> its development begins at the commencement of the second year, according to Monti<sup>8)</sup> in the third or fourth

<sup>8)</sup> Anatomie. Modena 1891.

year, according to Engel<sup>1)</sup> after the twelfth year, according to R. Hartmann<sup>2)</sup> during puberty, and according to Tillaux<sup>3)</sup> after the twelfth year. Zuckerkandl, who does not regard the frontal sinus as derived from an ethmoidal cell, writes: "In the new-born infant no trace of a frontal sinus is visible." Miháľkovics states that "the frontal sinus arises out of the recess of the middle meatus; until the fourth year this protuberance remains small, and even at puberty it has only attained the size of a pea." According to Poirier<sup>4)</sup> the frontal sinus is first seen about the end of the second year and is then difficult to demonstrate; about the seventh year it attains the size of a pea and ceases to grow between the fifteenth and twentieth year. Spee<sup>5)</sup> makes the following statement: "Whilst the first rudiment of a frontal sinus is visible soon after the first year in the form of a shallow depression, it does not shew any considerable increase until the time immediately preceding puberty, its final size being attained, as a rule, about the twentieth year."

According to Langer-Toldt<sup>6)</sup> "the earliest sign of a frontal sinus is seen about the end of the first year in the form of a shallow depression. The depth of this cavity increases slowly, so that at the sixth year it has hardly reached the size of a pea. The development of the frontal sinus progresses more rapidly about the eleventh or twelfth year". Chiari<sup>7)</sup> says in his text-book: "The frontal sinus is completely absent in the new-born infant, and at puberty it is about the size of a pea". Zarnico<sup>8)</sup> writes in his text-book: "The frontal sinuses are not present at birth. Their development begins towards the end of the first year. About the sixth or seventh year their size is about that of a pea".

In Hajek's<sup>9)</sup> text book we find only an enumeration of the results of Killian's embryological researches.

According to Chiarugi<sup>10)</sup> the frontal sinuses are derived from the anterior ethmoidal cells; they are not distinctly visible until the eighth year, and attain the final stage of their development between the fifteenth and twentieth year, or even later.

In other German, French and English text-books no accurate data referring to the frontal sinuses in childhood are to be found. From the statements repeated above it will be obvious, that the views of the different authors vary and are often contradictory; the only uniform statement as to the measurements of the sinus is "the size of a pea", but the authors differ as to when this size is attained. I have been unable to trace any further anatomical data, more especially, any measurements of the frontal sinuses, either in anatomical or rhinological text-books.

<sup>10)</sup> Anatomie. 1904.

We will proceed to discuss the few publications dealing with skiagrams of the frontal sinus, viz. the researches of Eicken, Haike and myself. Five skiagrams from my monograph on the frontal sinus have been included in this atlas. In a skull of three years, two skulls of three and a half, one of four, one of six, one of eight and a half, one of nine, one of twelve and one of fourteen years, I have described the early and the later form of the sinus; the difference between these two forms consisting in the extent of their development in the frontal region. The early form of the frontal sinus was situated laterally of the olfactory cleft and shewed considerable variation in size. Eicken<sup>1)</sup> found an ethmoidal cell of distinctly frontal character only in one skull of seven years. Smaller frontal ethmoidal cells were seen by him in skulls under seven years. In skulls of twelve, fourteen and fifteen years frontal sinuses of varying magnitude were observed. Haike<sup>2)</sup> investigated the accessory sinuses in several children, also in diseased conditions of the sinuses. To this part of his work we shall refer later on. His skiagrams were taken both in the fronto-occipital and in the lateral direction. As regards the frontal sinus, he saw "the earliest evidence of independent frontal sinuses twice in girls of  $3\frac{1}{2}$  years".

Haike also examined the frontal sinuses of children aged, respectively 5, 7,  $7\frac{1}{2}$ ,  $8\frac{1}{2}$ , 10,  $10\frac{1}{2}$ ,  $11\frac{1}{4}$ , 12,  $13\frac{1}{4}$ ,  $13\frac{1}{2}$ , 14, and 16 years, and usually found fairly large cavities, those in children of  $7\frac{1}{2}$ ,  $8\frac{1}{2}$  and more years shewing a considerable size. The skiagrams of diseased frontal sinuses and their importance will be considered in the second section, when we will also deal with the case of Killian<sup>3)</sup> who opened up a diseased frontal sinus in a child one year and three months of age.

After this literary retrospect it will be convenient to summarize the results of our investigations, so far as they deal with the frontal sinus. The following tables contain concise details as to the heads examined, their age, the planes of section, and the measurements of the sinuses in each case, together with remarks and references to the number of the illustration. The first table comprises the data obtained from the sections, the second table those derived from skiagrams of bony skulls.

In connection with these tables we will briefly summarize the measurements of the frontal sinus at different ages.

In the *first year* (newborn infants, children of 1,  $4\frac{1}{4}$ , 5,  $6\frac{1}{2}$ , 8 and 12 months) the height of the frontal sinus was between  $3\frac{1}{2}$  and 8 mm, its length between 3 and 9 mm, and its width between 2 and 6 mm.

In the *second year* (children of 15, 18 and 24 months) the height of the frontal sinus was between  $4\frac{1}{2}$  and 9 mm, its length between 4 and  $5\frac{1}{2}$  mm, and its width between 3 and 4 mm.

In the *third year* (children of 3) the height of the frontal sinus was between 14 and 18 mm, its length between 11 and 16 mm, and its width between 5 and 6 mm.

In the *fourth year* (children of 3 and a half years) the height of the frontal sinus was 6½ mm, its length 6 mm and its width 5 mm.

In the *sixth year* (child of 6) the height of the frontal sinus was between 17 and 18 mm, its length between 10 and 13 mm and its width between 11 and 12 mm.

In the *eighth year* (child of 7½) the height of the frontal sinus varied between 14 and 17 mm, its length between 4 and 11 mm, and its width between 7 and 9 mm.

Our skiagrams of the frontal region of bony skulls have furnished the following results:

In the *second year* (children of 15 months) the height of the frontal sinus varied from 3 to 3½ mm, its width from 5 to 5½ mm.

In the *fourth year* (children of 3½ years) the height of the frontal sinus varied from 4 to 6 mm, its width from 4 to 6 mm.

In the *sixth year* (child of 6 years) the height of the frontal sinus varied from 6 to 8½ mm, its width from 6 to 8½ mm.

In the *ninth year* (children of  $8\frac{1}{2}$  and 9 years) the height of the frontal sinus varied from 10 to 22 mm, its width from 10 to 29 mm.

In the *twelfth year* (child of 12 years) the height of the frontal sinus was 17 mm and its width 20 mm.

In the *thirteenth year* (child of 13 years) the height of the frontal sinus varied from 10 to 13 mm and its width from 16 to 18 mm.

In the *fourteenth year* (children of  $13\frac{1}{2}$  and 14 years) the height of the frontal sinns varied from 10 to 18 mm and its width from 10 to 21 mm.

In the *fifteenth year* (child of 15 years) the height of the frontal sinus varied from 5 to 11 mm and its width from 5 to 8 mm.

At the age of *eighteen* (youth of 18 years) the height of the frontal sinus varied from 6 to 15 mm and its width from 13 to 26 mm.

At the age of *nineteen* (youth of 19 years) the height of the frontal sinus varied from 16 to 21 mm and its width from 21 to 24 mm.

In passing I may mention that in some of the sections of heads one and two years old the expression "early form of the frontal sinus, frontal recess" has been used. This term serves to describe the stage of development of the frontal sinus which occurs in the first years of childhood, before it has reached the basal part of the squamous portion of the frontal bone, and prior to the formation of air spaces. With regard to this question detailed histological investigations are now being carried out in which we hope to elucidate the conditions prior to the extension of the frontal sinus into the region of the forehead.

From the above data, as well as the illustrations of coronal, horizontal and longitudinal vertical sections, it will be seen that we have figured the form, situation and size of the frontal sinus from its first appearance until the eighth year of life. In addition skiagrams are given of children and youths from 15 months to 19 years of age. Older investigations have thus been amplified and corrected in many details. With the practical employment in surgical work of these data, measurements and topographical illustrations, we shall deal in the second section of this summary.

## 2. The Maxillary Antrum.

The data found in literature as to the development of the maxillary antrum and as to its condition in childhood and youth are far more scanty than those referring to the frontal sinns. According to Gegenbaur<sup>1)</sup> "the first rudiment of the maxillary antrum is the earliest to appear, being seen even before the middle of foetal life; but it does not attain its complete development until comparatively late; nor does it shew any considerable growth before the second year of childhood. Even in the new-born infant the infraorbital furrow lies laterally of the developing maxillary antrum, whilst at a later stage it is situated on its superior aspect."

According to Miháľkovics<sup>2)</sup> "the epithelial depression which marks the earliest rudiment of the maxillary antrum is first observed in the middle of the third month;

<sup>1)</sup> Lehrbuch der Anatomie. 1883, 1890.

<sup>2)</sup> l. c.

in the fourth and fifth month the maxillary recess has become deeper; in the sixth or seventh month it develops into an elongated passage. In the fourth month the maxillary antrum is  $\frac{1}{2}$  mm, in the fifth month 5 mm in depth." According to Zuckerkandl<sup>1)</sup> "the germ of the maxillary antrum is represented by a shallow pit which stretches backwards from the lachrymal sulcus to the alveolus of the second molar. Laterally, the germ of the antrum reaches as far as the

<sup>1)</sup> l. c.

infraorbital canal, the lower aspect of which it hardly exceeds. In the second year of life the maxillary antrum has become deeper; anteriorly, it still only reaches as far as the infraorbital canal, but posteriorly it has already passed beyond it. The cavity has also increased in depth by this time, since it has grown down to the ridge of insertion of the concha. In the third or fourth year the anterior portion of the antrum has also advanced laterally beyond the infraorbital canal. In the seventh year this portion of the antrum reaches midway between the infraorbital canal and the malar process. In the eighth or ninth year the antrum has penetrated into the malar process, and has reached the limit of its growth in the transverse direction. The depth and height of the antrum are considerably influenced by the descent and eruption of the teeth; in these dimensions therefore the antrum does not attain its definite form until the end of the second dentition.

According to Langer-Toldt<sup>1)</sup> "in the fifth month of foetal life the antrum begins to develop in the form of an epithelial depression; at birth it already represents a well-marked recess."

According to Chiari<sup>2)</sup> "at the fifth month a depression 5 mm in depth is present. Until the sixth year the antrum remains spherical and very small. It then assumes the form of a triangular pyramid and gradually increases owing to the growth of the body of the maxilla, the descent of the permanent teeth and the absorption of the spongy substance of the body of the maxilla."

According to Zarnico<sup>3)</sup> "in the new-born infant the maxillary antrum is a very narrow fossa which reaches laterally to the infraorbital canal. The remainder of the body of the maxilla is filled up with dental germs and spongy bone substance. Even after the eruption of the milk-teeth the germs of the permanent teeth leave but little space for the antrum. Only at the commencement of the second dentition, about the seventh year, it begins to grow more rapidly; when the molars break through and the facial skull increases in height, the antrum soon assumes a notable size."

Haike<sup>4)</sup> carried out measurements of some skulls. In a child of  $1\frac{1}{2}$  years he found an antrum 4 to 5 mm wide and 20 mm long; in a child of 2, an antrum 8 mm wide and 25 mm long; in a child of  $2\frac{1}{2}$ , an antrum 4 mm wide and 9 mm long; in a child of 5, an antrum 16 mm wide and 25 mm long. According to his statement the floor of the antrum has attained its greatest depth at or about the twelfth year. Haike also took skiagrams of several children, some of whom had diseased antra — this we shall refer to subsequently —; the children were aged, respectively, 18 months, 2,  $2\frac{1}{2}$ ,  $2\frac{3}{4}$ ,  $3\frac{1}{2}$ , 4,  $4\frac{1}{2}$ , 7, 8,  $10\frac{3}{4}$ , 11,  $11\frac{3}{4}$ , 15 and 16 years. In describing his skiagrams he gives no measurements of the antra. With the value of the skiagram from the diagnostic and surgical point of view, we shall deal in the second section.

The above data are not very specialised; in Zuckerkandl's detailed description

---

<sup>1)</sup> l. c.

<sup>2)</sup> l. c.

<sup>3)</sup> l. c.

<sup>4)</sup> l. c.

of the development of the antrum in the first years of childhood no measurements are given, whilst in the measurements performed by Haike in four heads the height of the antrum is not stated.

With regard to the foetal germ of the antrum we dispose of one observation: in the coronal section of a foetus of  $6\frac{1}{2}$  months an antrum 3 mm long and  $1\frac{1}{2}$  mm wide (Pl. 1 *sm*) was found.

In connection with the foregoing table we will briefly summarize the measurements of the maxillary antrum according to the age of the specimen.

In the *first year* (new-born infant, and children of 1, 2, 4,  $4\frac{1}{4}$ ,  $4\frac{1}{2}$ , 5,  $5\frac{1}{2}$ ,  $6\frac{1}{2}$ , 7, 8, 11 and 12 months) the length of the antrum varied between 5 and 19 mm, the height between 3 and 9 mm, and the width between  $2\frac{1}{2}$  and 8 mm.

In the *second year* (children of 18 and 24 months) the length of the antrum was between 10 and 12 mm, the height between 8 and 9 mm, and the width between 3 and 7 mm.

In the *third year* (child of 3 years) the antrum was 23 mm long, 13 mm high, and 13 mm wide.

In the *fourth year* (child of 3½) it was 26 mm long, 13 mm high and 12 mm wide.

In the *eighth year* (child of 7½) it was 38 mm long, 23 mm high and 20 mm wide.

The figures are reproduced in natural size and shew in coronal, horizontal and longitudinal sections the topographical relations and form of the maxillary antrum from birth to the eighth year.

The concluding remarks of the chapter on the frontal sinus (see page 6) hold good also for this chapter.

## The Ethmoidal Cells.

With regard to the development of the ethmoid bone, its cellular spaces and foetal ossifications, a number of data are found in the text books of anatomy.

In addition, the reader is referred to the investigations of Seydel<sup>1)</sup>, Mihákovics<sup>2)</sup>, Killian<sup>3)</sup> and Zuckerkandl<sup>4)</sup> who have made a particular study of the development of the nasal cavity, its conchae and meatuses, and of the structural development of the ethmoidal labyrinth. In the chapter on the frontal sinus the theory of those investigators was mentioned who consider the frontal sinus to have been developed from an anterior ethmoidal cell, the so-called "frontal cell". For this reason we will not enter into the details of these embryological investigations, nor discuss the relations of the osseous plates of the ethmoid bone and the inter-turbinal meatuses to the ethmoidal cells. We were not able, however, to discover in the literature on the subject any further data as to the anterior and posterior ethmoidal cells and their measurements in childhood. Zarucio<sup>5)</sup> says in his textbook: "The ethmoidal cells are existent in the new-born infant in the form of narrow pouches and very soon attain a considerable size". Haike<sup>6)</sup> has published skiagraphical investigations of the ethmoidal cells which however deal more with diseased cavities and which will be considered in detail in the second section.

The foregoing tables shew the age, plane of section and measurements of the anterior and posterior ethmoidal cells, together with some remarks relative to them.

In connection with these tables we will summarize the measurements of the anterior and posterior ethmoidal cells according to the age of the specimen.

In the *first year* (new-born infant and children of 1,  $4\frac{1}{4}$ , 5,  $5\frac{1}{2}$ ,  $6\frac{1}{2}$ , 8, 11 and 12 months) the length of the anterior ethmoidal cells varied between 1 and 9 mm, their height between 1 and 8 mm, and their width between 1 and 6 mm. The length of the posterior ethmoidal cells varied between 2 and 10 mm, their height between 2 and 8 mm and their width between  $1\frac{1}{2}$  and 8 mm.

In the *second year* (children of 8 and 24 months) the length of the anterior ethmoidal cells varied between  $2\frac{1}{2}$  and  $4\frac{1}{2}$  mm, their height between 4 and 10 mm, and their width between  $1\frac{1}{2}$  and 4 mm. The length of the posterior ethmoidal cells was 4 mm, their height 5 mm, and their width 3 mm.

In the *third year* (child of 3) the length of the anterior ethmoidal cells was between 6 and 7 mm, their height between 6 and 7 mm, and their width between 3 and 4 mm. The length of the posterior ethmoidal cells was between 6 and 7 mm, their height between 6 and 7 mm, and their width between 3 and 4 mm.

In the *fourth year* (child of  $3\frac{1}{2}$ ) the length of the anterior ethmoidal cells varied between 3 and 8 mm, their height between  $3\frac{1}{2}$  and 11 mm, and their width between 3 and 6 mm. The length of the posterior ethmoidal cells varied between  $3\frac{1}{2}$  and 11 mm, their height between  $3\frac{1}{2}$  and 10 mm, and their width between 3 and 11 mm.

In the *sixth year* (child of 6) the length of the anterior ethmoidal cells varied

<sup>3)</sup> l. c.

<sup>4)</sup> l. c.

<sup>5)</sup> l. c.

<sup>6)</sup> l. c.

between 5 and 6 mm, their height between 8 and 10 mm, and their width between 6 and 7 mm.

In the *eighth year* (child of  $7\frac{1}{2}$ ), the length of the anterior ethmoidal cells varied between 5 and 6 mm, their height between 8 and 13 mm, and their width was 7 mm; the length of the posterior ethmoidal cells was between 11 and 17 mm, their width between 6 and 9 mm, and their height was 10 mm.

With regard to the results of our investigations of the anterior and posterior ethmoidal cells, which comprise the period from birth down to the eighth year, I would repeat the concluding remarks of the chapters on the frontal sinus and maxillary antrum (Pp. 6, 10).

### The Sphenoidal Sinus.

The development of the sphenoidal sinus has received a comparatively detailed description in anatomical text-books, particularly as regards the influence of the sphenoidal conchae upon the development of the sphenoidal sinus and the posterior ethmoidal cells, as well as the ossification and consolidation of the sphenoidal conchae. The investigations of Toldt<sup>1)</sup>, Zuckerkandl<sup>2)</sup> and Spee<sup>3)</sup> which deal with this subject are described in the treatises of these authors, whilst the statements of Toldt relative to the sphenoidal conchae have also been adopted by rhinological writers. Toldt regards the sphenoidal sinuses in the light of the most posteriorly situated ethmoidal cells, a view with which Zuckerkandl however does not agree. We will not enter into the details of this question, as it is only of embryological interest.

Merkel<sup>4)</sup> dates the first appearance of the sphenoidal sinus to the seventh year.

According to Mihálikovics<sup>5)</sup> "the first rudiments of the sphenoidal sinus are seen in the third month, but it is not until the sixth or seventh year that the body of the sphenoid bone forms the wall of the cavity."

According to Zuckerkandl<sup>6)</sup> "in the new-born infant and in young children the orifice of the germ of the sphenoidal sinus is narrowed by a semicircular fold of mucous membrane projecting from below. In the third year the sphenoidal sinus attains the size of a pea."

Spee<sup>7)</sup> states that the sphenoidal sinus is originally an open diverticulum of the nasal cavity; similarly, Chiarugi<sup>8)</sup> writes that the sphenoidal sinus is a diverticulum of the nasal cavity which develops about the third year.

According to Chiari<sup>9)</sup> "traces of the sphenoidal sinus are seen as early as the third foetal month in the shape of a double saccule, which soon afterwards increases in size."

The statement of Zarnico<sup>1)</sup> is to the effect that "in the new-born infant the cavity is as large as a pin's head and opens through a fine canal at the level of Santorini's Coneha. In the third year it then begins to grow more rapidly, and at puberty has reached the sphenoccipital synchondrosis".

Haike<sup>2)</sup> examined the sphenoidal sinus by means of skiagrams: in the sixth year the sinus was of the size of a bean; in the eighth and fourteenth year it was of considerable size: in a youth of sixteen the sinus was represented by a depression measuring 3 mm in the longitudinal direction, identification of the depression being obtained by the introduction of a probe. With the conclusions to be drawn from the results of skiagraphic examination of the sphenoidal sinus, we shall deal in the second section.

The foregoing table gives the age, plane of section, and measurements of the sphenoidal sinus and its ostium, together with a few remarks.

In connection with this table we will give a brief summary of the measurements of the sphenoidal sinus and its ostium according to the different ages.

In the *first year* (new-born infants and children of 1, 2, 4,  $4\frac{1}{2}$ , 5,  $5\frac{1}{2}$ ,  $6\frac{1}{2}$ , 7 and 8 months) the height of the sphenoidal sinus varied from 1 to 6 mm, its length from 1 to 5 mm, and its width from 1 to 6 mm. The diameter of the circular sphenoidal ostium was between  $\frac{1}{2}$  and 2 mm.

In the *second year* (children of 14, 15, 18 and 24 months) the height of the sphenoidal sinus varied from 2 to 6 mm, its length from 3 to 5 mm, and its width from 2 to 7 mm. The diameter of the circular sphenoidal ostium was between 1 and  $1\frac{1}{2}$  mm.

In the *third year* (child of 3) the height of the sphenoidal sinus was 6 mm, its length 6 mm, and its width 9 mm. The diameter of the circular sphenoidal ostium was 2 mm.

In the *fourth year* (child of  $3\frac{1}{2}$ ) the height of the sphenoidal sinus varied between  $4\frac{1}{2}$  and 6 mm, its length between  $3\frac{1}{2}$  and 5 mm, its width was 7 mm. The diameter of the circular sphenoidal ostium was  $1\frac{1}{2}$  mm.

In the *sixth year* (child of 6) the length of the sphenoidal sinus varied between 6 and 7 mm, its height was 10 mm, and its width 12 mm. The diameter of the circular sphenoidal ostium was  $1\frac{1}{2}$  mm.

In the *eighth year* (child of  $7\frac{1}{2}$  years) the height of the sphenoidal sinus was between 8 and 12 mm, its length between 12 and 13 mm, its width was 11 mm. The width of the oval sphenoidal ostium was 4 mm.

In concluding this summary of data relative to the sphenoidal sinus and its ostium we would again refer to the concluding remarks of the chapters on the frontal sinus (page 6), the maxillary antrum (page 10) and the ethmoidal cells (page 12).

## II.

We will now proceed to supplement the anatomical results given in the first chapter by certain practical remarks. Since the publications dealing with affec-

tions of the accessory sinuses in childhood are steadily increasing, we may conclude that diseases of these cavities occur more frequently in childhood than was generally recognised in the past. It should be regarded as an established fact that when children suffer from frequent attacks of acute cold in the head, some of the accessory sinuses are also affected, and that as a rule infectious diseases attack the partially developed accessory sinuses. In the first years of childhood it is difficult to ascertain such disease of the different cavities; besides, at this age, the possibility of treating such affections is somewhat limited.

It need hardly be pointed out that many fatal cases of this disease remain obscure, and that only a small number of *post-mortem* reports has hitherto been published. In 62 out of 394 autopsies performed on children, Harke<sup>1)</sup> opened the accessory sinuses; he found them diseased in 52 cases which were between 9 months and 15 years of age: in 47 cases the maxillary antra, in 3 the ethmoidal cells, and in 2 the sphenoidal sinuses were affected. In an autopsy performed on a child of 3 years, Harke found empyema of the maxillary antrum, whilst the frontal and sphenoidal sinuses were not developed. Wolff<sup>2)</sup> performed *post mortem* examinations in two children of 3, two of 5 and one of 6 years; the sphenoidal sinus was undeveloped in both children of 3, one child of 5 and one of 6 years. Wertheim<sup>3)</sup> found well-developed frontal sinuses in a child of two years and two months; in a child of five, the ethmoidal cells were diseased and the sphenoidal sinuses well-developed, in another child of five all the accessory sinuses were developed, whilst in a child of eight the frontal and sphenoidal sinuses were absent.

The foregoing table (Page 15) comprises the cases which have come under our notice, in which diseases of the accessory sinuses were ascertained and treated in children. With exception of the cases of Haike all the cases published suffered from scarlatinal affections of the nose.

With regard to the diagnostic employment of *electrical transillumination* of the frontal sinus and maxillary antrum, and to the *skiagraphic examination* of the accessory sinuses in childhood, the reader is referred to my monograph on the frontal sinus<sup>4)</sup> where these questions are discussed in detail. Our investigations which were performed on 1200 skulls demonstrated the unreliability of electrical transillumination. For by this method absence of both frontal sinuses was diagnosed in 30 per cent., absence of the right frontal sinus in 10 per cent., of the left frontal sinus in 10 per cent.; yet skiagraphical examination carried out on the same skulls revealed absence of both frontal sinuses in only 5 per cent., absence of the right frontal sinus in less than 1 per cent, and of the left frontal sinus in the same ratio. We also noted the drawbacks of skiagraphic examination and discussed why it can not be regarded as an infallible method; but as to its superiority to transillumination there can be no doubt. The determination of the absence or the extent of the frontal sinuses by means of skiagraphy has greatly assisted the

<sup>3)</sup> Arch. f. Laryngologie, vol. XI.

<sup>4)</sup> l. c.

progress of surgical treatment; in diagnosis, also, skiagraphy represents a valuable aid. Needless to say, the chief importance attaches to the clinical investigation and to the result of rhinoscopic examination. The same argument holds good for the maxillary antrum, where electrical transillumination and skiagraphy are also employed as aids to diagnosis, and for the ethmoidal cells and the sphenoidal sinus with reference to skiagraphy. Corresponding views on the electrical transillumination of the frontal sinus and the maxillary antrum of children are expressed by Haike<sup>1)</sup>: "Whilst even in adults the results obtained by this method must be used with caution, it proves utterly unreliable in children." We will therefore limit ourselves to a consideration of the skiagraphic examination of the accessory sinuses in children. With regard to the frontal sinus, even in adults skiagraphy has furnished erroneous results; thus in the cases of Albrecht<sup>2)</sup>, Wassermann<sup>3)</sup>, Chiari<sup>4)</sup>, Ónodi<sup>5)</sup> and others, the frontal sinus appeared fogged or obscured in the skiagram, yet this appearance was not confirmed by the operation.

Obviously, the employment of skiagraphy for purposes of diagnosis is still more limited in childhood. Haike himself says: "The difficulties in diagnosing empyema of the frontal sinus in children are even greater than those encountered in adults. In drawing any conclusions from the skiagram still greater care is required in order to avoid errors. For we observe more often than in the fully developed cavity a certain amount of blurring and indistinctness of the outlines, although the sinus may be perfectly healthy. In consequence of this indistinctness of the pictures, which is due to the anatomical condition of the developing frontal sinus, it is almost always advisable to supplement the picture by a lateral skiagram, and occasionally even this may not clear up every doubt. In view of these difficulties in judging the picture, it becomes necessary, so far as possible, to consider also the clinical features of the case, and in older children to employ the other methods of examination in order to secure the diagnosis."

Besides the skiagrams of the normal frontal sinus by Haike which were mentioned previously, only a few cases have been published where the skiagram indicated disease of the frontal sinus, viz. a case of 13 and one of 16 years. Cases of disease of the sinus, treated surgically, in younger children have not been recorded by Haike<sup>6)</sup>. In the published cases which have come to our knowledge the diseased condition of the frontal sinus was determined and operation performed without the aid of skiagraphy; the only exception being the case of Killian<sup>7)</sup>, a child of twelve, where the antrum, the frontal sinus and the ethmoidal cells were undoubtedly blurred in the skiagram. In the first years of childhood the value of skiagraphy and the conclusions to be drawn from it, so far as the frontal sinus is concerned, are very limited; this is shewn by our results and pictures where, with few exceptions, the sinus in the first years only reaches the lower

<sup>7)</sup> l. c.

limit of the basal portion of the squama or exists as a definite cavity only in the inferior basal portion of the squama. As a rule, therefore, a skiagram taken during the first years of childhood will shew not only the frontal sinus, but also the adjoining anterior ethmoidal cells; in case of their being diseased, it is therefore also applicable. From what has already been said, it will hardly be necessary to point out, that in the first place the clinical signs and, wherever possible, inspection of the nasal cavity should be taken into consideration. In such cases however, where the frontal sinus can be ascertained in the frontal region, and particularly where there is unilateral disease of the frontal sinus, the skiagram may be of the same value as in the adult.

In the first year we found the largest *frontal sinus* to be 9 mm long, 8 mm high, and 6 mm wide; the early form of the frontal sinus attained the base of the squamous portion of the frontal bone towards the end of the first year. In the second year we found the largest frontal sinus to be 9 mm high,  $5\frac{1}{2}$  mm long, and 7 mm wide. Early in the second year, in a child of 15 months, we saw the frontal sinus situated in the basal part of the squamous portion; in another child of the same age the skiagram of the forehead shewed a frontal sinus measuring 3 to  $3\frac{1}{2}$  mm in height and 5 to  $5\frac{1}{2}$  mm in width. In a child of 15 months Killian<sup>1)</sup> opened the diseased frontal sinus. In a child of three and a half years we found the frontal sinus  $6\frac{1}{2}$  mm high, 6 mm long and 5 mm wide, in skiagrams the frontal sinus was shewn to be 6 to 9 mm high and 4 to 6 mm wide. In a case of E. Meyer<sup>1)</sup>, a child of the same age, the diseased frontal sinus was opened and cured. These facts prove that even in the first years the frontal sinus may sometimes be seen in the skiagram; its diseased condition may thus be recognised and radically cured.

In the cases of Preysing<sup>2)</sup> and Lange<sup>3)</sup> the diseased frontal sinus was opened and cured in children of five years. In the sixth year we found a frontal sinus measuring 17 to 18 mm in height, 10 to 13 mm in length and 11 to 12 mm in width, and in one case the skiagram shewed a frontal sinus 6 to  $8\frac{1}{2}$  mm high and 6 to  $8\frac{1}{2}$  mm wide. In Killian's<sup>4)</sup> case disease of the frontal sinus was cured by operation in a child of six. In the case of Lange<sup>5)</sup> the diseased frontal sinus was successfully opened in a child six and a quarter years old. In the cases of Hoffmann<sup>6)</sup> and Killian<sup>7)</sup> the diseased frontal sinus was cured by operation in children of seven years. At seven and a half years of age we found a frontal sinus 14 to 17 mm high, 4 to 11 mm long and 7 to 9 mm wide. At eight and a half years a skiagram of the forehead shewed the frontal sinus measuring 10 to 22 mm in height and 10 to 29 mm in width. In Tilley's<sup>8)</sup> case the diseased frontal sinus was successfully opened in a child of nine.

<sup>8)</sup> l. c.

In our case, disease of the frontal sinus was cured by operation in a child of nine and a half years. The foregoing are the cases that have come to our knowledge in children under ten. In the following years the frontal sinuses shew a varying degree of development in the frontal region: this is illustrated by the skiagrams published by Haike<sup>1)</sup>, as well as by the figures and measurements given by us. The experiences which have been gained hitherto are quite insufficient to allow a definite conclusion to be drawn as to the diagnostic value of skiagraphy in children; there can be no doubt that on the whole it is a valuable supplementary method of diagnosis. On the other hand, it is a necessary consequence of the peculiarities in the form and situation of the frontal sinus which have already been noted that the value of such skiagrams taken in early childhood is more limited and that their drawbacks are perhaps greater than in adults. For this reason, great importance attaches to the clinical signs and to the result of rhinoscopic examination. The difficulties encountered in such examinations are due to the narrowness of the nasal cavity and the necessarily incomplete character of such investigations in the first years of life; endonasal inspection revealing the pathological secretion, but failing to determine its origin. In such cases occasionally the skiagram considered in conjunction with the clinical signs may give a decisive indication for the mode of treatment.

In the majority of the cases quoted previously it will be remembered, that surgical treatment was carried out. Among these the case of E. Meyer<sup>2)</sup> is unique, for here, in a child of three and a half years, the maxillary antrum was first opened and from here the frontal sinus was exposed together with the ethmoidal cells. Otherwise the region of the frontal sinus with the ethmoidal cells was opened by an arc-shaped incision beginning at the root of the nose and following the line of the eye-brow. In the first years of childhood the frontal sinus can not be reached from the forehead owing to its peculiar shape and situation which have been described previously. The exceptions which have already been mentioned and illustrated, cannot of course be taken into account. In young children, therefore, the frontal sinus is exposed from a spot close to the inner canthus where the frontal bone, the nasal bone and the frontal process of the maxilla meet. The line of incision already mentioned together with this spot serve as a guide not only for operations on the frontal sinus, but also for exposing and clearing the ethmoidal labyrinth and the sphenoidal sinus. This question will be considered in detail subsequently. Naturally, in all those cases where the skiagram and the age of the patient point to the existence of the sinus in the frontal region, the ordinary method of resection and radical operation of the sinus is employed. Particularly for surgical treatment the skiagram is valuable, since it allows us to determine the presence or absence of the frontal sinus in the region of the forehead and to gain an idea as to its extent.

The *Maxillary Antrum* is the cavity where diseased conditions have been observed most often. We have shewn that the measurements of the antrum at birth, and in the first, second, third, fourth and eighth year vary considerably,

<sup>1)</sup> l. c.

<sup>2)</sup> l. c.

the longitudinal diameter however being greatest. Until the fourth year the height of the cavity was intermediate between its length and its width. In the fourth and eighth years, however, the width of the antrum had already exceeded the height and was second only to its length. The skiagrams of children taken by Haike<sup>1)</sup> have already been mentioned; besides normal antra, he saw diseased ones in children of  $4\frac{1}{2}$ , 7, 8,  $10\frac{3}{4}$  and 11 years. In such pictures the antrum appeared blurred and ill-defined. In some cases the skiagram furnished a decisive argument in favour of an operation. Yet Haike<sup>2)</sup> himself states that in one case the dark shadow in the region of the antrum did not indicate the presence of pus in the cavity, whilst in another case no difference was observed between the two antra, although there was a collection of serous fluid in one of them. He remarks as follows: "Naturally, careful consideration of the pictures will protect us against mistakes due to faults in the photograph and other causes, which might give a semblance of disease. Here again, we would point out that the greatest importance attaches to the clinical signs and to the results of rhinological examination, although we admit that skiagraphy represents a valuable aid to diagnosis. Of the different methods of examination those chiefly employed are endonasal puncture and irrigation of the antrum. Taken in conjunction with these methods, the skiagram may convey information as to the extent and depth of the antrum. In the adult, puncture of the antrum is usually performed from the lower meatus, from where the endonasal resection of the antrum is also carried out. In the first years of childhood this method is beset by several difficulties." Miháľkovics was one of the first to point out the narrowness of the lower meatus and its impermeability: "In children the meatus is very low and narrow, the free edge of the lower concha meets the floor of the nasal cavity, its thick mucous membrane entirely occludes the lower meatus; the middle meatus alone is permeable, so that in the infant only this meatus and the corresponding portion of the common nasal passage can serve as respiratory space."

According to Zarnico<sup>3)</sup> exposure of the maxillary antrum in young children prior to the second dentition is best attempted from the middle meatus. It should not be performed from the other spots until after the eruption of the first permanent molars."

Haike<sup>4)</sup> remarks "that until the time when the floor of the cavity has quite, or almost, attained its permanent depth, i. e. about the twelfth year, it is hardly accessible for puncture from the lower meatus. One might easily penetrate into the bone below the antrum." Cases are recorded where even in adults attempts at puncture from the lower meatus failed, the canula perforating the thin wall of the antrum and emerging in the tissues of the cheek. Thus, too, in a child of  $11\frac{3}{4}$  years, Haike<sup>5)</sup> records the canula having penetrated into the cheek, whilst in a child of 8 it perforated the spongy bone below the antrum.

---

<sup>1)</sup> l. c.

<sup>2)</sup> l. c.

<sup>4)</sup> l. c.

<sup>2)</sup> l. c.

<sup>3)</sup> l. c.

Our descriptions and illustrations of the morphological conditions of the maxillary antrum shew that puncture should be performed from the middle meatus, although in exceptional cases we have found the antrum adjoining the lower meatus even in the first years of childhood. At the same time we would point out the comparatively slight extent of the antrum in the transverse direction. This is important, since if the canula were introduced too forcibly, it might easily penetrate the opposite, lateral wall of the cavity and injure the cheek. In children under ten years of age, radical operation of the antrum has repeatedly been performed, viz. by E. Meyer<sup>1)</sup> in a child of  $3\frac{1}{2}$ , by Killian in a child of 6, by Haenel<sup>2)</sup> in a child of  $6\frac{1}{2}$ , and by Hoffmann<sup>3)</sup> in a child of 7 years, the treatment proving successful. Our illustrations in natural size and the measurements of the antrum recorded will prove of use both in endonasal and in radical operations on this cavity.

Disease of the *Ethmoidal Cells* has usually been observed in conjunction with disease of the frontal and sphenoidal sinus and of the maxillary antrum.

Skiagrams have been published by Killian<sup>4)</sup> of the case of a child of twelve, where the frontal sinus, ethmoidal cells and maxillary antrum appeared markedly blurred; also in the cases of Haike<sup>5)</sup>, children of 4,  $4\frac{1}{2}$ , 8,  $10\frac{3}{4}$ , 11 and 12 years, in all of which the ethmoidal cells appeared obscured and indistinct; in two of these cases only the ethmoidal cells were affected, in the remaining five the antrum was also diseased. In the first years of childhood it is difficult to distinguish the ethmoidal cells from the early form of the frontal sinus; the frontal sinus can only be differentiated, if it is already situated in the region of the forehead. In consequence of the difficulty of rhinoscopic examination at this age, Haike<sup>6)</sup> considers "that a reliable diagnosis of ethmoidal affections in children can only be obtained by skiagraphy." On the other hand, he does not over-estimate the value of the skiagram, as is shewn by the following passage: "In young children the picture of the ethmoidal cells in the skiagram is so narrow that it is sometimes difficult to arrive at a definite diagnosis; thus, even moderate congestion of the mucous membrane may veil the lumina of the small ethmoidal cells"; and again; "With regard to the question whether the anterior or posterior ethmoidal cells are affected, the skiagram can give no more information in children than in the adult".

The greater part of the cases mentioned by us were cured by operation without consulting the skiagram. Together with the clinical signs and the evidence of rhinoscopy, the skiagram may doubtless be employed as a valuable diagnostic aid, provided that its drawbacks are duly considered. Our pictures and measurements shew that even in the first years both the anterior and the posterior ethmoidal cells are fairly well developed. The narrowness of the nasal cavity and its meatuses explains why it is difficult to expose the ethmoidal cells by endonasal

---

<sup>1)</sup> l. c.

<sup>2)</sup> l. c.

<sup>3)</sup> l. c.

<sup>4)</sup> l. c.

<sup>5)</sup> l. c.

<sup>6)</sup> l. c.

operation: endonasal treatment thus being practically limited to irrigation or suction. The situation and extent of the ethmoidal cells however provide arguments in favour of radical operation. This operation was performed in one case through the maxillary antrum, in most of the other cases together with resection of the frontal sinus. Obviously, the ethmoidal labyrinth may also be exposed by resection of the orbital plate from the orbit. For such operations, the morphological conditions of the anterior and posterior ethmoidal cells described and illustrated by us will be found instructive and useful. In the case of E. Meyer<sup>1)</sup> the diseased ethmoidal cells of a child of 3½ years were successfully exposed and cleared out from the maxillary antrum. In the cases of Preysing<sup>2)</sup> and Lange<sup>3)</sup> — children of five years — the diseased ethmoidal cells were opened together with the frontal sinus, the affection being cured. In the cases of Preysing<sup>4)</sup>, children of six, the diseased ethmoidal cells as well as the sphenoidal sinus, in Killians<sup>5)</sup> case, also a child of six, the diseased ethmoidal cells and the frontal sinus, were operated and cured. In Lange's<sup>6)</sup> case, a child of 6½ years, the diseased ethmoidal cells only, and in Haenel's<sup>7)</sup> case, also a child of 6½ years, the ethmoidal cells together with the frontal sinus were cured by surgical treatment. In Hoffmann's<sup>8)</sup> case, a child of seven, the diseased ethmoidal cells as well as the frontal sinus were cured by operation. We have mentioned these cases in children under ten years of age, since the success obtained with them is a strong argument in favour of radical operation. Complications may of course arise from the orbit, the disease of the ethmoidal cells spreading to the orbit: in such cases, this must also receive surgical treatment.

With regard to the *Sphenoidal Sinus*, its disease has been observed far more rarely in children. By skiagraphic examination Haike twice shewed the absence of the sphenoidal sinus in children of 2½ and 4 years respectively, whilst in skiagrams of a child of 6 and one of 8 years he found decisive evidence of their existence. He mentions one case, a patient aged 15½ years, where the sphenoidal sinus appeared obscured. Diagnosis of a diseased condition of the sphenoidal sinus has to deal with the same difficulties which have been mentioned for the frontal sinus and the ethmoidal cells. Haike<sup>9)</sup> himself remarks: "It is true, that the scope of the skiagram is considerably restricted." In view of the difficulty of endonasal investigation Haike hopes to obtain conclusive evidence from the skiagram alone. Yet he is fain to admit, "that we must always remain conscious of the limitations of the method. In older children, on the other hand, one ought always to be guided more by the result of clinical examination." The rule that the clinical signs should be considered principally and the skiagram only be used

<sup>9)</sup> l. c.

as a secondary aid to diagnosis, is particularly applicable to diseases of the sphenoidal sinus in children. Our experience on this subject is but scanty. In the two cases published by Preysing<sup>1)</sup>, in children of 6 years, the sphenoidal sinus was successfully operated upon together with the diseased ethmoidal cells; in Haenel's<sup>2)</sup> case, also a child of six, where all the accessory sinuses were well developed and diseased, a cure was effected by radical operation. We are of opinion that the details of the sphenoidal sinus described and figured in this book will prove instructive for operations carried out in the first years of childhood; resection of this sinus should be performed through the ethmoidal labyrinth. In later years, and also in certain exceptional cases which we have seen in young children, endonasal treatment of the sphenoidal sinus may be attempted. Its success will depend upon the degree of development of the sinus.

We conclude the synopsis of our results in the hope that the sections reproduced in natural size and the accurate measurements given in every case may have served to extend and amplify our knowledge of the anatomy and development of the accessory sinuses in childhood, and that this more accurate information will prove helpful in the diagnosis and surgical treatment of the affections of these sinuses occurring in childhood.

## Plate 1.

Natural size. — Foetus of  $6\frac{1}{2}$  months.

*sm* maxillary antrum, *cea* ethmoidal cell, *ci* lower concha, *mni* lower meatus, *cm* middle concha, *mm* middle meatus, *pu* uncinate process, *cs* upper concha, *mns* upper meatus, *s* septum.

Coronal section through the head of a foetus  $6\frac{1}{2}$  months old, shewing the nasal fossae separated by the septum (*s*), the lower (*ci*), middle (*cm*) and upper (*cs*) concha, the lower (*mni*), middle (*mm*) and upper (*mns*) meatus, the maxillary antrum (*sm*) and the anterior ethmoidal cell (*cea*). The maxillary antrum (*sm*) is 3 mm long and  $1\frac{1}{2}$  mm wide.

## Tafel 2.

Natürliche Grösse. — 8 Monat alter Fötus.

*rf* recessus frontalis, *hs* hiatus semilunaris, *pu* processus uncinatus, *cm* concha media, *mns* meatus narium superior, *cs* concha superior, *t* tuba Eustachii, *cr* cysta retropharyngealis.

Der Sagittalschnitt eines 8 Monat alten Fötus zeigt die laterale Nasenwand nach Entfernung der mittleren Nasenmuschel. Man sieht die Ansatzlinie der mittleren Nasenmuschel (*cm*), durch ihre Entfernung ist freigelegt das Gebiet des hiatus semilunaris (*hs*), welchen oben die Lamelle der bulla ethmoidalis und unten der processus uncinatus (*pu*) begrenzt. Oberhalb des scharf abgegrenzten vordersten Teiles des hiatus semilunaris (*hs*) ist der ausgeprägt vorhandene recessus frontalis (*rf*) zu sehen, welcher sich in einer Ausdehnung von  $4\frac{1}{2}$  mm nach oben und vorne erstreckt. Oberhalb der Ansatzlinie der mittleren Muschel (*cm*) ist der obere Nasengang (*mns*) und die obere Nasenmuschel (*cs*), rückwärts die Mündung der Eustachischen Röhre (*t*) und die in der Tafel 3 erwähnte Retropharyngealzyste (*cr*) zu übersehen.

## Planche 2.

Grandeur nature. — Foetus de 8 mois.

*rf* recessus frontal, *hs* hiatus semilunaire, *pu* processus uncinatus, *cm* cornet moyen, *mns* méat supérieur, *cs* cornet supérieur, *t* trompe d'Eustache, *cr* kyste rétropharyngé.

Coupe sagittale d'un foetus de 8 mois montrant la paroi latérale de la fosse nasale après section du cornet moyen. On voit la ligne d'insertion du cornet moyen (*cm*). Par la section du cornet moyen la région de l'hiatus semilunaire (*hs*) est devenue visible. Ses limites sont en haut la lame de la bulle ethmoïdale et en bas le processus uncinatus (*pu*). Au dessus de la partie antérieure de l'hiatus semilunaire (*hs*) bien limitée se trouve le recessus frontal (*rf*) très marqué, s'étendant sur une longueur de  $4\frac{1}{2}$  millim. en haut et en avant. Au dessus de la ligne d'insertion du cornet moyen (*cm*) se trouvent le méat supérieur (*mns*) et le cornet supérieur (*cs*). En arrière, l'ouverture de la trompe d'Eustache (*t*) et le kyste rétropharyngé (*cr*) mentionné sur le planche 3.

## Plate 2.

Natural size. — Foetus of 8 months.

*rf* frontal recess, *hs* semilunar hiatus, *pu* uncinate process, *cm* middle concha, *mns* upper meatus, *cs* upper concha, *t* Eustachian tube, *cr* retropharyngeal cyst.

Longitudinal vertical section through the head of a foetus 8 months old, shewing the lateral aspect of the nasal fossa after removal of the middle concha. The ridge of insertion of the middle concha (*cm*) is visible. Through the removal of this concha the region of the semilunar hiatus (*hs*) has been exposed. It is bounded above by the lamina of the ethmoidal bulla, below by the uncinate process (*pu*). Above the sharp anterior margin of the semilunar hiatus (*hs*) the well marked frontal recess (*rf*) may be seen extending upwards and forwards for a distance of  $4\frac{1}{2}$  mm. Above the ridge of insertion of the middle concha (*cm*) are the upper meatus (*mns*) and upper concha (*cs*). Further backwards, the orifice of the Eustachian tube (*t*) and the retro-pharyngeal cyst (*cr*) mentioned in the description of plate 3 are visible.

### Tafel 3.

Natürliche Grösse. — 8 Monat alter Fötus.

*ci* concha inferior, *mni* meatus narium inferior, *cm* concha media, *mm* meatus narium medius, *cs* concha superior, *mns* meatus narium superior, *mnsr* meatus narium supremus. *cr* cystis retro-pharyngealis, *cp* cystis palatina.

Der Sagittalschnitt eines 8 Monat alten Fötus zeigt die laterale Wand der Nasenhöhle, die untere (*ci*), mittlere (*cm*) und obere (*cs*), Nasenmuschel und den Rest der obersten Nasenmuschel begrenzt von dem kurzen Rest des obersten Nasenganges (*mnsr*), ferner den unteren (*mni*), mittleren (*mm*) und oberen (*mns*) Nasengang. Der Schnitt zeigt ausserdem zwei kongenitale Schleimzysten im Gebiete des weichen Gaumens und des Retropharynx. Die Retropharyngealzyste (*cr*) hat eine Ausdehnung von 10 mm Länge, 13 mm Höhe und 16 mm Breite, die Gaumenzyste (*cp*) hat eine Ausbreitung von 9 mm Länge, 9 mm Höhe und 10 mm Breite.

### Planche 3.

Grandeur nature. — Foetus de 8 mois.

*ci* cornet inférieur, *mni* méat inférieur, *cm* cornet moyen, *mm* méat moyen, *cs* cornet supérieur, *mns* méat supérieur, *mnsr* meat supreme, *cr* kyste rétropharyngé, *cp* kyste palatin.

Sur cette coupe sagittale d'un foetus de 8 mois, on voit la paroi latérale de la fosse nasale, les cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*) et le reste du quatrième cornet. On voit les méats suprême (*mnsr*), supérieur (*mns*), moyen (*mm*) et inférieur (*mni*). Sur la coupe on voit de plus deux kystes congénitaux, l'un dans le voile du palais et l'autre dans le cavum. Le kyste du pharynx (*cr*) a une longueur de 10 millim., une hauteur de 13 millim. et une largeur de 16 millim. Les dimensions du kyste palatin (*cp*) sont respectivement 9 millim., 9 millim., et 10 millim.

### Plate 3.

Natural size. — Foetus of 8 months.

*ci* lower concha, *mni* lower meatus, *cm* middle concha, *mm* middle meatus, *cs* upper concha, *mns* upper meatus, *mnsr* uppermost meatus, *cr* retropharyngeal cyst, *cp* palatine cyst.

Longitudinal vertical section through the head of a foetus of 8 months, shewing the lateral wall of the nasal fossa, the lower (*ci*), middle (*cm*), and upper (*cs*) concha, and a vestige of the uppermost concha bounded by vestiges of the short uppermost meatus (*mnsr*); the lower (*mni*), middle (*mm*), and upper (*mns*) meatus are also visible. The section shews, besides, two congenital mucous cysts situated respectively in the palatal and retro-pharyngeal regions. The retro-pharyngeal cyst (*cr*) is 10 mm long, 13 mm high, and 16 mm wide; the palatal cyst (*cp*) is 9 mm long, 9 mm high, and 10 mm wide.

## Tafel 4.

Natürliche Grösse. — Neugeborenes Kind.

*rf* recessus frontalis, *pu* processus uncinatus, *hs* hiatus semilunaris, *lbe* lamina bullae ethmoidalis, *cm* concha media, *mns* meatus narium superior, *cs* concha superior, *csr* concha suprema.

Der Sagittalschnitt des Kopfes eines Neugeborenen zeigt die laterale Nasenhöhlenwand nach der Entfernung der mittleren Nasenmuschel. Man sieht die Ansatzlinie der mittleren Nasenmuschel (*cm*), durch ihre Entfernung ist freigelegt das Gebiet des hiatus semilunaris (*hs*), welchen oben die Lamelle der bulla ethmoidalis (*lbe*) und unten der processus uncinatus (*pu*) begrenzt. Oberhalb des scharf abgegrenzten vordersten Teiles des hiatus semilunaris (*hs*) ist der ausgeprägt vorhandene recessus frontalis (*rf*) zu sehen, welcher sich in einer Ausdehnung von  $3\frac{1}{2}$  mm nach oben und vorne erstreckt. Oberhalb der Ansatzlinie der mittleren Muschel (*cm*) ist der obere Nasengang (*mns*), die obere Nasenmuschel (*cs*) und der Rest der obersten Nasenmuschel (*csr*) zu übersehen.

## Planche 4.

Grandeur nature. — Enfant nouveau-né.

*rf* recessus frontal, *pu* processus uncinatus, *hs* hiatus semilunaire, *lbe* lame de la bulle ethmoïdale, *cm* cornet moyen, *mns* méat supérieur, *cs* cornet supérieur, *csr* quatrième cornet.

Coupe sagittale d'un enfant nouveau-né montrant la paroi latérale de la fosse nasale après section du cornet moyen. On voit la ligne d'insertion du cornet moyen. Par la section du cornet moyen la région de l'hiatus semilunaire limitée en haut par la lame de la bulle ethmoïdale et en bas par le processus uncinatus est devenue visible. Au dessus de la partie antérieure de l'hiatus semilunaire (*hs*), très marquée, se voit très distinctement le recessus frontal (*rf*), qui s'étend sur une longueur de  $3\frac{1}{2}$  millim. en haut et en avant. On voit au dessus de la ligne d'insertion du cornet moyen (*cm*) le méat supérieur (*ms*), le cornet supérieur (*cs*) et le reste du quatrième cornet (*csr*).

## Plate 4.

Natural size. — New-born infant.

*rf* frontal recess, *pu* uncinate process, *hs* semilunar hiatus, *lbe* lamina of ethmoidal bulla, *cm* middle concha, *mns* upper meatus, *cs* upper concha, *csr* uppermost concha.

Longitudinal vertical section through the head of a new-born infant, shewing the lateral wall of the nasal fossa after removal of the middle concha. The ridge of insertion of the middle concha (*cm*) is visible. Through the removal of the middle concha the region of the semilunar hiatus (*hs*) has been exposed; it is bounded above by the lamina of the ethmoidal bulla (*lbe*), below by the uncinate process (*pu*). Above the clearly defined anterior portion of the semilunar hiatus (*hs*) a well marked frontal recess (*rf*) may be seen extending upwards and forwards for a distance of  $3\frac{1}{2}$  mm. Above the ridge of insertion of the middle concha (*cm*), the upper meatus (*mns*), upper concha (*cs*), and vestiges of the uppermost concha (*csr*) are visible.

## Tafel 5.

Natürliche Grösse. — Neugeborenes Kind.

*sm* sinus maxillaris, *pu-hs* processus uncinatus, hiatus semilunaris, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *ci* concha inferior, *mni* meatus narium inferior, *cm* concha media, *mm* meatus narium medius, *cs* concha superior, *mns* meatus narium superior, *s* septum.

Der Frontalschnitt des Kopfes eines Neugeborenen zeigt die enge linke Nasenhöhle, an ihrer äusseren Wand die untere (*ci*), die mittlere (*cm*) und die obere (*cs*) Nasenmuschel, den unteren (*mni*), den mittleren (*mm*) und den oberen (*mns*) Nasengang. Im mittleren Nasengange (*mm*) ist der hiatus semilunaris (*hs*) begrenzt vom processus uncinatus (*pu*), mit der Mündung der Kieferhöhle (*sm*) zu übersehen. Die Kieferhöhle (*sm*) liegt im Bereiche des unteren Nasenganges (*mni*) und der unteren Muschel (*ci*), ist 7 mm lang, 4 mm hoch und 3 mm breit. Die vorderen Siebbeinzellen (*cea*) haben eine Ausdehnung von 1—2½ mm, die hintere Siebbeinzelle (*cep*) ist 5 mm lang, 2½ mm hoch und 1½ mm breit.

## Planche 5.

Grandeur nature. — Enfant nouveau-né.

*sm* sinus maxillaire, *pu-hs* processus uncinatus, hiatus semilunaire, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *ci* cornet inférieur, *mni* méat inférieur, *cm* cornet moyen, *mm* méat moyen, *cs* cornet supérieur, *mns* méat supérieur, *s* septum.

La coupe frontale de la tête d'un nouveau-né montre la paroi latérale de la fosse nasale gauche étroite, les cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*), les méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*). Dans le méat moyen (*mm*) on peut voir l'hiatus semilunaire (*hs*) limité par le processus uncinatus (*pu*) et l'ostium du sinus maxillaire (*sm*). Le sinus maxillaire (*sm*) se trouve au niveau du méat inférieur (*mni*) et du cornet inférieur (*ci*) et est long de 7 millim., haut de 4 millim. et large de 3 millim. Les cellules ethmoïdales antérieures (*cea*) ont une étendue de 1 à 2½ millim.; la cellule ethmoïdale postérieure a 5 millim. de longueur, 2½ millim. de hauteur et 1½ millim. de largeur.

## Plate 5.

Natural size. — New-born infant.

*sm* maxillary antrum, *pu-hs* uncinat process, semilunar hiatus, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *ci* lower concha, *mni* lower meatus, *cm* middle concha, *mm* middle meatus, *cs* upper concha, *mns* upper meatus, *s* septum.

Coronal section through the head of a new-born infant, shewing the narrow left nasal fossa, and on its lateral wall the lower (*ci*), middle (*cm*) and upper (*cs*) concha, and the lower (*mni*), middle (*mm*) and upper (*mns*) meatus. In the middle meatus (*mm*) the semilunar hiatus (*hs*) is seen bounded by the uncinat process (*pu*) and opening into it, the maxillary antrum (*sm*). The maxillary antrum (*sm*) is situated near the lower meatus (*mni*) and the lower concha (*ci*); it is 7 mm long, 4 mm high and 3 mm wide. The anterior ethmoidal cells (*cea*) are between 1 and 2½ mm in size. The posterior ethmoidal cell (*cep*) is 5 mm long, 2½ mm high and 1½ mm wide.

Natural size. — Child 1 month old.

## Tafel 12.

Natürliche Grösse. — 1 Monat altes Kind.

*rf* recessus frontalis, *be* bulla ethmoidalis, *hs, pu* hiatus semilunaris, processus uncinatus, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *ci* concha inferior, *cm* concha media, *mm* meatus narium medius, *cs* concha superior, *ms* meatus narium superior.

Der Sagittalschnitt des 1 Monat alten Kopfes zeigt die Stirnhöhle in ihrer frühen Form als recessus frontalis (*rf*), die vorderen (*cea*) und hinteren (*cep*) Siebbeinzellen, einen Teil der unteren (*ci*), mittleren (*cm*) und der oberen (*cs*) Nasenmuschel und einen Teil des mittleren (*mm*) und oberen (*ms*) Nasenganges. Der recessus frontalis (*rf*) ist  $4\frac{1}{2}$  mm hoch,  $3\frac{1}{2}$  mm lang und 3 mm breit, er mündet direkt in den hiatus semilunaris (*hs*), welcher zwischen der bulla ethmoidalis und dem processus uncinatus (*pu*) zu sehen ist. Die vorderen Siebbeinzellen (*cea*) sind 2—6 mm hoch, 3—4 mm lang und  $2\frac{1}{2}$  mm breit. Die hinteren Siebbeinzellen (*cep*) sind 2—3 mm hoch,  $2\frac{1}{2}$ —3 mm lang und 2—4 mm breit.

## Planche 12.

Grandeur nature. — Enfant de 1 mois.

*rf* recessus frontal, *be* bulle ethmoïdale, *hs, pu* hiatus semilunaire, processus uncinatus, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *ci* cornet inférieur, *cm* cornet moyen, *mm* méat moyen, *cs* cornet supérieur, *ms* méat supérieur.

Coupe sagittale de la tête d'un enfant de 1 mois montre le sinus frontal dans la forme primitive d'un recessus frontal (*rf*), les cellules ethmoïdales antérieures (*cea*) et postérieures (*cep*), une partie des cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*) et une partie des méats moyen (*mm*) et supérieur (*ms*). Le recessus frontal (*rf*) est haut de  $4\frac{1}{2}$  millim., long de  $3\frac{1}{2}$  millim. et large de 3 millim. Il se termine directement dans l'hiatus semilunaire (*hs*) que l'on peut voir entre la bulle ethmoïdale et le processus uncinatus (*pu*). Les cellules ethmoïdales antérieures (*cea*) ont une hauteur de 2 à 6 millim., une longueur de 3 à 4 millim. et une largeur de 2 à  $2\frac{1}{2}$  millim. Les cellules ethmoïdales postérieures (*cep*) ont une hauteur de 2 à 3 millim., une longueur de  $2\frac{1}{2}$  à 3 millim. et une largeur de 2 à 4 millim.

## Plate 12.

Natural size. — Child 1 month old.

*rf* frontal recess, *be* ethmoidal bulla, *hs, pu* semilunar hiatus, uncinat process, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *ci* lower concha, *cm* middle concha, *mm* middle meatus, *cs* upper concha, *ms* upper meatus.

Longitudinal vertical section through the head of a child 1 month old, shewing the frontal sinus in its earlier developmental stage of a frontal recess (*rf*), the anterior (*cea*) and posterior (*cep*) ethmoidal cells, parts of the lower (*ci*), middle (*cm*) and upper (*cs*) concha and of the lower (*mm*), middle (*mm*) and upper (*ms*) meatus. The frontal recess (*rf*) is  $4\frac{1}{2}$  mm high,  $3\frac{1}{2}$  mm long and 3 mm wide. It opens directly into the semilunar hiatus (*hs*) which is seen enclosed between the ethmoidal bulla (*be*) and the uncinat process (*pu*). The anterior ethmoidal cells (*cea*) are 2 to 6 mm in height, 3 to 4 mm in length and 2 to  $2\frac{1}{2}$  mm in width. The posterior ethmoidal cells (*cep*) are 2 to 3 mm in height,  $2\frac{1}{2}$  to 3 mm in length and 2 to 4 mm in width.

Natürliche Grösse. — 1 Monat altes Kind.

*ss* sinus sphenoidalis, *os* ostium sphenoidale.

Der Frontalschnitt eines 1 Monat alten Kopfes zeigt die Keilbeinhöhle (*ss*) im Keilbeinkörper. sie ist 3 mm hoch,  $2\frac{1}{2}$  mm breit und 2 mm lang, ihre Mündung, das ostium sphenoidale (*os*) bildet eine  $1\frac{1}{4}$  mm weite runde Öffnung. An diesem Kopfe ist die Kieferhöhle 8 mm lang, 7 mm hoch und  $2\frac{1}{2}$  mm breit. Die vorderen Siebbeinzellen sind 3—5 mm lang, 2—5 mm hoch und  $2-2\frac{1}{2}$  mm breit. Die hintere Siebbeinzelle ist 5 mm lang, 4 mm hoch und  $3\frac{1}{2}$  mm breit.

## Planche 13.

Grandeur nature. — Enfant de 1 mois.

*ss* sinus sphénoïdal, *os* ostium du sinus sphénoïdal.

La coupe frontale de la tête d'un enfant de 1 mois montre le sinus sphénoïdal dans le corps de l'os sphénoïdal; il a une hauteur de 3 millim., une largeur de  $2\frac{1}{2}$  millim. et une longueur de 2 millim. L'ostium du sinus sphénoïdal (*os*) forme une ouverture ronde, large de  $1\frac{1}{4}$  millim. Sur cette tête le sinus maxillaire a 8 millim. de long, 7 millim. de haut et  $2\frac{1}{2}$  millim. de large. La cellule ethmoïdale antérieure a de 3 à 5 millim. de long, de 2 à 5 millim. de haut et de 2 à  $2\frac{1}{2}$  millim. de large. La cellule ethmoïdale postérieure a 5 millim. de longueur, 4 millim. de hauteur et  $3\frac{1}{2}$  millim. de largeur.

## Plate 13.

Natural size. — Child 1 month old.

*ss* sphenoidal sinus, *os* sphenoidal ostium.

Coronal section through the head of a child one month old, shewing the sphenoidal sinus (*ss*) situated within the body of the sphenoid bone; the sinus is 3 mm high,  $2\frac{1}{2}$  mm wide and 2 mm long. Its orifice, the sphenoidal ostium (*os*), is a circular aperture,  $1\frac{1}{4}$  mm in diameter. The maxillary antrum of this skull is 8 mm long, 7 mm high and  $2\frac{1}{2}$  mm wide. The anterior ethmoidal cells are 3 to 5 mm long, 2 to 5 mm high and 2 to  $2\frac{1}{2}$  mm wide. The posterior ethmoidal cell is 5 mm long, 4 mm high and  $3\frac{1}{2}$  mm wide.

*rf* recessus frontalis, *cea* cellula ethmoidalis anterior, *sm* sinus maxillaris, *mni* meatus narium inferior, *ci* concha inferior, *mm* meatus narium medius, *pu* processus uncinatus, *cm* concha media.

Der Frontalschnitt eines 1 Monat alten Kopfes zeigt die laterale Wand der Nasenhöhle, die untere (*ci*) und mittlere (*cm*) Nasenmuschel, den unteren (*mni*) und mittleren (*mm*) Nasengang. Im mittleren Nasengange (*mm*) ist der processus uncinatus (*pu*) und der hiatus semilunaris zu sehen, oberhalb des mittleren Nasenganges (*mm*) ist der 6 mm hohe, 5 mm lange und 2 mm breite recessus frontalis (*rf*) zu sehen, ferner im Bereiche des mittleren Nasenganges (*mm*) vordere Siebbeinzellen (*cea*) und im Bereiche des unteren Nasenganges (*mni*) die Kieferhöhle (*sm*).

## Planche 14.

Grandeur nature. — Enfant de 1 mois.

*rf* recessus frontal, *cea* cellule ethmoïdale antérieure, *sm* sinus maxillaire, *mni* méat inférieur  
*ci* cornet inférieur, *mm* méat moyen, *pu* processus uncinatus, *cm* cornet moyen.

Coupe frontale d'une tête d'enfant de 1 mois montrant la paroi latérale de la fosse nasale, les cornets inférieur (*ci*) et moyen (*cm*), les méats inférieur (*mni*) et moyen (*mm*). Dans le méat moyen (*mm*) on peut voir le processus uncinatus (*pu*) et l'hiatus semilunaire; au-dessus du méat moyen (*mm*) on voit le recessus frontal (*rf*) haut de 6 millim., long de 5 millim. et large de 2 millim., de plus au niveau du méat moyen (*mm*) se trouvent les cellules ethmoïdales antérieures (*cea*) et au niveau du méat inférieur (*mni*) le sinus maxillaire (*sm*).

## Plate 14.

Natural size. — Child 1 month old.

*rf* frontal recess, *cea* anterior ethmoidal cell, *sm* maxillary antrum, *mni* lower meatus, *ci* lower concha, *mm* middle meatus, *pu* uncinate process, *cm* middle concha.

Coronal section through the head of a child one month old, shewing the lateral wall of the nasal fossa, the lower (*ci*) and middle (*cm*) concha, the lower (*mni*) and middle (*mm*) meatus. In the middle meatus (*mm*) the uncinate process (*pu*) and the semilunar hiatus are visible. Above the middle meatus (*mm*) is the frontal recess (*rf*), measuring 6 mm in height, 5 mm in length and 2 mm in width. Adjoining the middle meatus (*mm*) are the anterior ethmoidal cells (*cea*), adjoining the lower meatus (*mni*) the maxillary antrum (*sm*).

Natürliche Grösse. — 1 Monat altes Kind.

*rf* recessus frontalis, *pu* processus uncinatus, *cea* cellula ethmoidalis anterior, *hs* hiatus semilunaris, *cep* cellula ethmoidalis posterior, *mni* meatus narium inferior, *ci* concha inferior, *mm* meatus narium medius, *cm* concha media, *mns* meatus narium superior, *t* tuba Eustachii.

Der Sagittalschnitt eines 1 Monat alten Kopfes zeigt den unteren (*mni*), den mittleren (*mm*) und den oberen (*mns*) Nasengang, die untere (*ci*) und die mittlere (*cm*) Nasenmuschel. Durch das Wegfallen des vordersten Teiles der mittleren Muschel (*cm*) ist der hiatus semilunaris (*hs*) zu sehen, begrenzt vom processus uncinatus (*pu*) und der bulla ethmoidalis (*cea*). Im Bereiche des oberen Nasenganges (*mns*) ist die hintere Siebbeinzelle (*cep*) und in der Linie des unteren Nasenganges (*mni*) hinten die tuba Eustachii (*t*) zu sehen. Die Frühform der Stirnhöhle, der recessus frontalis (*rf*) ist 5 mm hoch,  $4\frac{1}{2}$  mm breit und  $3\frac{1}{2}$  mm lang, er mündet am oberen vorderen Teile des hiatus semilunaris (*hs*). Die vordere Siebbeinzelle (*cca*) ist  $4\frac{1}{2}$  mm lang, 4 mm hoch und  $3\frac{1}{2}$  mm breit. Die hintere Siebbeinzelle (*cep*) ist 5 mm lang,  $3\frac{1}{2}$  mm breit und 3 mm hoch.

## Planche 17.

Grandeur nature. — Enfant de 1 mois.

*rf* recessus frontal, *pu* processus uncinatus, *cea* cellule ethmoïdale antérieure, *hs* hiatus semilunaire, *cep* cellule ethmoïdale postérieure, *mni* méat inférieur, *ci* cornet inférieur, *mm* méat moyen, *cm* cornet moyen, *mns* méat supérieur, *t* trompe d'Eustache.

Coupe sagittale d'une tête de 1 mois montrant les méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*), les cornets inférieur (*ci*) et moyen (*cm*). Par la section de la partie antérieure du cornet moyen, on peut voir l'hiatus semilunaire limité par la processus uncinatus (*pu*) et la bulle ethmoïdale (*be*). Au niveau du méat supérieur (*mns*) on peut voir la cellule ethmoïdale postérieure (*cep*) et dans la direction du méat inférieur (*mni*), la trompe d'Eustache (*t*). La forme précoce du sinus frontal (*sf*), le recessus frontal, a 5 millim. de haut,  $4\frac{1}{2}$  millim. de large et  $3\frac{1}{2}$  millim. de long; il s'ouvre à la partie antéro-supérieure de l'hiatus semilunaire (*hs*). La cellule ethmoïdale antérieure (*cea*) a  $4\frac{1}{2}$  millim. de long, 4 millim. de haut et  $3\frac{1}{2}$  millim. de large. La cellule ethmoïdale postérieure (*cep*) a 5 millim. de long,  $3\frac{1}{2}$  millim. de large et 3 millim. de haut.

## Plate 17.

Natural size. — Child of 1 month.

*rf* frontal recess, *pu* uncinate process, *cea* anterior ethmoidal cell, *hs* semilunar hiatus, *cep* posterior ethmoidal cell, *mni* lower meatus, *ci* lower concha, *mm* middle meatus, *cm* middle concha, *mns* upper meatus, *t* Eustachian tube.

Longitudinal vertical section through the head of a child aged one month, shewing the lower (*mni*), middle (*mm*) and upper (*mns*) meatus, and the lower (*ci*) and middle (*cm*) concha. Through the removal of the anterior part of the middle concha (*cm*) the semilunar hiatus (*hs*) has been exposed; it is enclosed between the uncinate process (*pu*) and the ethmoidal bulla (under *cea*). Adjoining the upper meatus (*mns*), is the posterior ethmoidal cell (*cep*); in a line with the lower meatus (*mni*) but further backwards, the Eustachian tube (*t*) is visible. The early developmental stage of the frontal sinus or frontal recess (*rf*) is 5 mm high,  $4\frac{1}{2}$  mm wide and  $3\frac{1}{2}$  mm long; it opens into the upper, anterior part of the semilunar hiatus (*hs*). The anterior ethmoidal cell (*cea*) is  $4\frac{1}{2}$  mm long, 4 mm high and  $3\frac{1}{2}$  mm wide. The posterior ethmoidal cell (*cep*) is 5 mm long,  $3\frac{1}{2}$  mm wide and 3 mm high.

---

## Tafel 21.

Natürliche Grösse. — 2 Monate altes Kind.

*sm* sinus maxillaris.

Der Sagittalschnitt des Kopfes eines 2 Monate alten Kindes zeigt die 11 mm lange, 4 mm breite und 3 mm hohe Kieferhöhle (*sm*).

## Planche 21.

Grandeur nature. — Enfant de 2 mois.

*sm* sinus maxillaire.

Coupe sagittale d'une tête d'enfant de 2 mois montrant le sinus maxillaire (*sm*), long de 11 millim., large de 4 millim. et haut de 3 millim.

## Plate 21.

Natural size. — Child of 2 months.

*sm* maxillary antrum.

Longitudinal vertical section through the head of a child aged 2 months, shewing the maxillary antrum (*sm*), which is 11 mm long, 4 mm wide and 3 mm high.

## Tafel 22.

Natürliche Grösse. — 4 Monate altes Kind.

*sm* sinus maxillaris, *mni* meatus narium inferior, *ci* concha inferior, *mm* meatus narium medius, *cm* concha media, *mns* meatus narium superior, *cs* concha superior, *os* ostium sphenoidale.

Der Frontalschnitt des Kopfes eines 4 Monate alten Kindes zeigt die 13 mm lange, 7 mm breite und 5 mm hohe Kieferhöhle, den unteren (*mni*), den mittleren (*mm*) und den oberen (*mns*) Nasengang, die untere (*ci*), die mittlere (*cm*) und die obere (*cs*) Nasenmuschel. Das ostium sphenoidale (*os*) ist kaum ein  $\frac{1}{2}$  mm weit und führt in eine 2 mm weite Keilbeinhöhle.

## Planche 22.

Grandeur nature. — Enfant de 4 mois.

*sm* sinus maxillaire, *mni* méat inférieur, *ci* cornet inférieur, *mm* méat moyen, *cm* cornet moyen, *mns* méat supérieur, *cs* cornet supérieur, *os* ostium du sinus sphénoïdal.

Coupe frontale d'une tête de 4 mois montrant le sinus maxillaire long de 13 millim., large de 7 millim. et haut de 5 millim., les méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*), les cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*). L'ostium du sinus sphénoïdal (*os*) a à peine  $\frac{1}{2}$  millim. de large et conduit dans un sinus sphénoïdal large de 2 millim.

## Plate 22.

Natural size. — Child of 4 months.

*sm* maxillary antrum, *mni* lower meatus, *ci* lower concha, *mm* middle meatus, *cm* middle concha, *mns* upper meatus, *cs* upper concha, *os* sphenoidal ostium.

Coronal section through the head of a child aged 4 months, shewing the maxillary antrum (*sm*), which is 13 mm long, 7 mm wide and 5 mm high, the lower (*mni*), middle (*mm*) and upper (*mns*) meatus and the lower (*ci*), middle (*cm*) and upper (*cs*) concha. The sphenoidal ostium (*os*), an orifice hardly  $\frac{1}{2}$  mm in diameter, leads into the sphenoidal sinus, which is 2 mm wide.

## Tafel 23.

Natürliche Grösse. — 4 Monate altes Kind.

*sm* sinus maxillaris.

Der Sagittalschnitt des Kopfes eines 4 Monate alten Kindes zeigt die 12 mm lange, 5 mm hohe und 6 mm breite Kieferhöhle (*sm*). An diesem Präparate ist das ostium sphenoidale  $\frac{1}{2}$  mm weit und führt in eine 3 mm weite Keilbeinhöhle.

## Planche 23.

Grandeur nature. — Enfant de 4 mois.

*sm* sinus maxillaire.

Coupe sagittale d'une tête d'enfant de 4 mois montrant le sinus maxillaire (*sm*) long de 12 millim., haut de 5 millim. et large de 6 millim. Sur cette préparation l'ostium du sinus sphénoïdal a  $\frac{1}{2}$  millim. de large et conduit dans un sinus sphénoïdal large de 3 millim.

## Plate 23.

Natural size. — Child of 4 months.

*sm* maxillary antrum.

Longitudinal vertical section through the head of a child aged 4 months, shewing the maxillary antrum (*sm*) which is 12 mm long, 5 mm high and 6 mm wide. In this specimen the sphenoidal ostium is  $\frac{1}{2}$  mm wide and leads into the sphenoidal sinus which is 3 mm wide.

## Tafel 25.

Natürliche Grösse. —  $4\frac{1}{4}$  Monate altes Kind.

*sf* sinus frontalis, *cea* cellula ethmoidalis anterior, *cn* cavum narium, *cm* concha media, *mm* meatus narium medius, *ci* concha inferior, *mni* meatus narium inferior, *dnl* ductus nasolacrimalis.

Der Frontalschnitt des  $4\frac{1}{4}$  Monate alten Kopfes zeigt die  $6\frac{1}{2}$  mm hohe,  $3\frac{1}{2}$  mm breite und 3 mm lange Stirnhöhle (*sf*), die vordere Siebbeinzelle (*cea*), den unteren (*mni*) und mittleren (*mm*) Nasengang, die untere (*ci*) und die mittlere (*cm*) Nasenmuschel. Im Bereiche des unteren Nasenganges (*mni*) ist der ductus nasolacrimalis (*dnl*) zu sehen.

## Planche 25.

Grandeur nature. — Enfant de 4 mois  $\frac{1}{4}$ .

*sf* sinus frontal, *cea* cellule ethmoïdale antérieure, *cn* cavité nasale, *cm* cornet moyen, *mm* méat moyen, *ci* cornet inférieur, *mni* méat inférieur, *dnl* conduit nasolacrimal.

Coupe frontale d'un crâne de 4 mois  $\frac{1}{4}$ , montrant le sinus frontal (*sf*) haut de  $6\frac{1}{2}$  millim., large de  $3\frac{1}{2}$  millim. et long de 3 millim., lacellule ethmoïdale antérieure (*cea*), les méats inférieur (*mni*) et moyen (*mm*), les cornets inférieur (*ci*) et moyen (*cm*). Au niveau du méat inférieur (*mni*) on peut voir le conduit nasolacrimal (*dnl*).

## Plate 25.

Natural size. — Child of  $4\frac{1}{4}$  months.

*sf* frontal sinus, *cea* anterior ethmoidal cell, *cn* nasal cavity, *cm* middle concha, *mm* middle meatus, *ci* lower concha, *mni* lower meatus, *dnl* nasal duct.

Coronal section through the head of a child aged  $4\frac{1}{4}$  months, shewing the frontal sinus (*sf*), measuring  $6\frac{1}{2}$  mm in height,  $3\frac{1}{2}$  mm in width and 3 mm in length, the anterior ethmoidal cell (*cea*), the lower (*mni*) and middle (*mm*) meatus, and the lower (*ci*) and middle (*cm*) concha. Adjoining the lower meatus (*mni*) the nasal duct (*dnl*) is visible.

Natürliche Grösse. —  $4\frac{1}{4}$  Monate altes Kind.

*sf* sinus frontalis, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *mm* meatus narium medius.

Der Horizontalschnitt eines  $4\frac{1}{4}$  Monate alten Kopfes ist am obersten Teile des mittleren Nasenganges (*mm*) geführt und zeigt in der Reihenfolge von vorne nach rückwärts die Stirnhöhle (*sf*), die vorderen (*cea*) und die hinteren (*cep*) Siebbeinzellen. Die Stirnhöhle (*sf*) ist 6 mm hoch,  $5\frac{1}{2}$  mm lang und 3 mm breit. Die vorderen Siebbeinzellen (*cea*) sind 4—5 mm hoch,  $3-4\frac{1}{2}$  mm lang und 2—4 mm breit. Die hinteren Siebbeinzellen (*cep*) sind 5 mm hoch, 3—5 mm lang und  $4\frac{1}{2}$  mm breit.

## Planche 28.

Grandeur nature. — Enfant de 4 mois  $\frac{1}{4}$ .

*sf* sinus frontal, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *mm* méat moyen.

Coupe horizontale d'une tête de 4 mois  $\frac{1}{4}$  passant par la partie supérieure du méat moyen (*mm*) et montrant, situés d'avant en arrière: le sinus frontal (*sf*), la cellule ethmoïdale antérieure (*cea*) et postérieure (*cep*). Le sinus frontal (*sf*) a 6 millim. de haut,  $5\frac{1}{2}$  millim. de long et 3 millim. de large. La cellule ethmoïdale antérieure (*cea*) a de 4 à 5 millim. de haut, de 3 à  $4\frac{1}{2}$  millim. de long et de 2 à 4 millim. de large. Les cellules ethmoïdales postérieures (*cep*) ont 5 millim. de haut, de 3 à 5 millim. de long et  $4\frac{1}{2}$  millim. de large.

## Plate 28.

Natural size. — Child of  $4\frac{1}{4}$  months.

*sf* frontal sinus, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *mm* middle meatus.

Horizontal section through the head of a child aged  $4\frac{1}{4}$  months. The section is cut through the uppermost part of the middle meatus and shews, from before backwards, the frontal sinus (*sf*), the anterior (*cea*) and posterior (*cep*) ethmoidal cells. The frontal sinus (*sf*) is 6 mm high,  $5\frac{1}{2}$  mm long and 3 mm wide. The anterior ethmoidal cells (*cea*) are 4 to 5 mm high, 3 to  $4\frac{1}{2}$  mm long and 2 to 4 mm wide. The posterior ethmoidal cells (*cep*) are 5 mm high, 3 to 5 mm long and  $4\frac{1}{2}$  mm wide.

*sm* sinus maxillaris, *dnl* ductus nasolacrimalis, *ci* concha inferior, *mni* meatus narium inferior.

Der Horizontalschnitt eines fünf Monate alten Kopfes zeigt in der Gegend des oberen Theiles der unteren Nasenmuschel (*ci*) die Kieferhöhle (*sm*) und den ductus nasolacrimalis (*dnl*), welcher in dem unteren Nasengange (*mni*) mündet. Die Kieferhöhle (*sm*) ist 14 mm lang, 6 mm breit und 5 mm hoch. An diesem Kopfe ist die Stirnhöhle  $7\frac{1}{2}$  mm hoch, 5 mm lang und 4 mm breit. Die vordere Siebbeinzellen sind 3—8 mm hoch,  $2\frac{1}{2}$ —6 mm lang und 2—5 mm breit. Die hintere Siebbeinzelle ist 9 mm lang, 6 mm hoch und 4 mm breit. Die Keilbeinhöhle ist 5 mm hoch,  $3\frac{1}{2}$  mm lang und 3 mm breit. Die Keilbeinhöhlenmündung ist 1 mm weit.

## Planche 33.

Grandeur nature. — Enfant de 5 mois.

*sm* sinus maxillaire, *dnl* conduit nasolacrimal, *ci* cornet inférieur, *mni* méat inférieur.

Coupe horizontale d'une tête de 5 mois, montrant, dans la région de la partie supérieure du cornet inférieur (*ci*), le sinus maxillaire (*sm*) et le conduit nasolacrimal (*dnl*) qui s'ouvre dans le méat inférieur (*mni*). Le sinus maxillaire (*sm*) a 14 millim. de long, 6 millim. de large et 5 millim. de haut. Le sinus frontal de cette tête a  $7\frac{1}{2}$  millim. de haut, 5 millim. de long et 4 millim. de large. La cellule ethmoïdale antérieure a de 3 à 8 millim. de haut, de  $2\frac{1}{2}$  à 6 millim. de long et de 2 à 5 millim. de large. La cellule ethmoïdale postérieure a 9 millim. de long, 6 millim. de haut et 4 millim. de large. Le sinus sphénoïdal a 5 millim. de haut,  $3\frac{1}{2}$  millim. de long et 3 millim. de large. L'ostium du sinus sphénoïdal a 1 millim. de large.

## Plate 33.

Natural size. — Child of 5 months.

*sm* maxillary antrum, *dnl* nasal duct, *ci* lower concha, *mni* lower meatus.

Horizontal section through the head of a child aged 5 months. Adjoining the upper portion of the lower concha (*ci*) are the maxillary antrum (*sm*) and the nasal duct (*dnl*); the latter opens into the lower meatus (*mni*). The maxillary antrum (*sm*) is 14 mm long, 6 mm wide and 5 mm high. The frontal sinus of this head is  $7\frac{1}{2}$  mm high, 5 mm long and 4 mm wide. The anterior ethmoidal cells are 3 to 8 mm high,  $2\frac{1}{2}$  to 6 mm long and 2 to 5 mm wide. The posterior ethmoidal cell is 9 mm long, 6 mm high and 4 mm wide. The sphenoidal sinus is 5 mm high,  $3\frac{1}{2}$  mm long and 3 mm wide. The sphenoidal ostium is 1 mm in diameter.

Natürliche Grösse. — 5 Monate altes Kind.

*sf* sinus frontalis, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *cn* cavum narium,  
*s* septum.

Der Horizontalschnitt des 5 Monate alten Kopfes ist am oberen Teile der Nasenhöhle geführt und zeigt die Stirnhöhle (*sf*), die vordere Siebbeinzelle (*cea*), die hintere Siebbeinzelle (*cep*), die Nasenhöhle (*cn*) und die Nasenscheidewand (*s*). Die Stirnhöhle (*sf*) ist 7 mm hoch,  $5\frac{1}{2}$  mm lang und 2 mm breit. Die vordere Siebbeinzellen (*cea*) sind 4—6 mm lang, 6—7 mm hoch und 2—5 mm breit. Die hintere Siebbeinzelle (*cep*) ist 9 mm lang, 8 mm hoch und  $4\frac{1}{2}$  mm breit.

## Planche 34.

Grandeur nature. — Enfant de 5 mois.

*sf* sinus frontal, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *cn* cavité nasale, *s* septum.

Coupe horizontale d'une tête de 5 mois passant par la partie supérieure de la cavité nasale, et montrant le sinus frontal (*sf*), la cellule ethmoïdale antérieure (*cea*), la cellule ethmoïdale postérieure (*cep*), la cavité nasale (*cn*) et le septum (*s*). Le sinus frontal (*sf*) a 7 millim de haut,  $5\frac{1}{2}$  millim de long et 2 millim. de large. La cellule ethmoïdale antérieure (*cea*) a de 4 à 6 millim. de long., de 6 à 7 millim. de haut et de 2 à 5 millim. de large. La cellule ethmoïdale postérieure (*cep*) a 9 millim. de long, 8 millim. de haut et  $4\frac{1}{2}$  millim. de large.

## Plate 34.

Natural size. — Child of 5 months.

*sf* frontal sinus, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *cn* nasal cavity, *s* septum.

Horizontal section through the skull of a child aged 5 months. The section is cut through the upper part of the nasal fossa and shews the frontal sinus (*sf*), the anterior (*cea*) and posterior (*cep*) ethmoidal cells, the nasal cavity (*cn*) and the septum (*s*). The frontal sinus (*sf*) is 7 mm high,  $5\frac{1}{2}$  mm long and 2 mm wide. The anterior ethmoidal cells (*cea*) are 4 to 6 mm long, 6 to 7 mm high and 2 to 5 mm wide. The posterior ethmoidal cell (*cep*) is 9 mm long, 8 mm high and  $4\frac{1}{2}$  mm wide.

Natürliche Grösse. — 5½ Monate altes Kind.

*sm* sinus maxillaris, *om* ostium maxillare, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *os* ostium sphenoidale, *mni* meatus narium inferior, *ci* concha inferior, *mm* meatus narium medius, *cm* concha media, *mns* meatus narium superior, *cs* concha superior, *mnsr* meatus narium supremus, *pu* processus uncinatus.

Der Frontalschnitt eines 5½ Monate alten Kopfes zeigt den unteren (*mni*), den mittleren (*mm*) und den oberen (*mns*) Nasengang, die untere (*ci*), mittlere (*cm*) und die obere (*cs*) Nasenmuschel, die Kieferhöhle (*sm*), die hinteren Siebbeinzellen (*cep*) und die Mündung der Keilbeinhöhle (*os*). Die 15 mm lange, 8 mm hohe und 7 mm breite Kieferhöhle (*sm*) ist im Bereiche des unteren Nasenganges (*mni*) und der unteren Muschel (*ci*) zu sehen mit ihrer Mündung (*om*), welche in den hiatus semilunaris führt, begrenzt vom processus uncinatus (*pu*). Das ostium sphenoidale (*os*) ist 1½ mm weit und führt in eine 2 mm weite Keilbeinhöhle.

## Planche 37.

Grandeur nature. — Enfant de 5 mois ½.

*sm* sinus maxillaire, *om* ostium du sinus maxillaire, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *os* ostium du sinus sphénoïdal, *mni* méat inférieur, *ci* cornet inférieur, *mm* méat moyen, *cm* cornet moyen, *mns* méat supérieur, *cs* cornet supérieur, *mnsr* méat suprême.

Coupe frontale d'une tête d'enfant de 5 mois ½ montrant les méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*), les cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*), le sinus maxillaire (*sm*), les cellules ethmoïdales postérieures (*cep*) et l'ostium du sinus sphénoïdal (*os*). On peut voir le sinus maxillaire (*sm*) long de 5 millim., haut de 8 millim., large de 7 millim., au niveau du méat inférieur (*mni*) et du cornet inférieur (*ci*), avec son ostium (*om*), qui conduit dans l'hiatus semilunaire, limité par le processus uncinatus (*pu*). L'ostium du sinus sphénoïdal (*os*) a 1½ millim. de large et conduit dans le sinus sphénoïdal large de 2 millim.

## Plate 37.

Natural size. — Child of 5½ months.

*sm* maxillary antrum, *om* maxillary ostium, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *os* sphenoidal ostium, *mni* lower meatus, *ci* lower concha, *mm* middle meatus, *cm* middle concha, *mns* upper meatus, *cs* upper concha, *mnsr* uppermost meatus, *pu* uncinuate process.

Coronal section through the skull of a child aged 5½ months, shewing the lower (*mni*), middle (*mm*) and upper (*mns*) meatus, the lower (*ci*), middle (*cm*) and upper (*cs*) concha, the maxillary antrum (*sm*), the anterior (*cea*) and posterior (*cep*) ethmoidal cells, and the orifice of the sphenoidal sinus (*os*). The maxillary antrum (*sm*) measures 15 mm in length, 8 mm in height and 7 mm in width. It can be seen in its relations with the lower meatus (*mni*) and lower concha (*ci*); its orifice (*om*) is also shewn, leading into the semilunar hiatus, which is bounded by the uncinuate process (*pu*). The sphenoidal ostium (*os*) is 1½ mm in diameter and leads into the sphenoidal sinus which is 2 mm wide.

## Tafel 38.

Natürliche Grösse. — 5½ Monate altes Kind.

*sf* sinus frontalis, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *hs* hiatus semilunaris, *pu* processus uncinatus, *be* bulla ethmoidalis, *mni* meatus narium inferior, *ci* concha inferior, *mm* meatus narium medius, *mns* meatus narium superior.

Der Sagittalschnitt eines 5½ Monate alten Kopfes zeigt die durchschnittene untere Nasenmuschel (*ci*), den unteren (*mni*), mittleren (*mm*) und den oberen (*mns*) Nasengang. Das Gebiet des hiatus semilunaris (*hs*) ist freigelegt mit der umgebenden bulla ethmoidalis (*be*) und dem processus uncinatus (*pu*). Oben in der Reihenfolge von vorne nach hinten ist die Stirnhöhle (*sf*), die vordere (*cea*) und die hintere (*cep*) Siebbeinzelle zu sehen. Die Frühform der Stirnhöhle (*sf*) ist 6½ mm lang, 5½ mm hoch und 4 mm breit, sie mündet breit am oberen Teile des hiatus semilunaris (*hs*). Die vorderen Siebbeinzellen (*cea*) sind 3—6 mm hoch, 3½—4 mm breit und 2½—3 mm lang. Die hintere Siebbeinzelle (*cep*) ist 5½ mm lang, 5 mm hoch und 4 mm breit.

## Planche 38.

Grandeur nature. — Enfant de 5 mois ½.

*sf* sinus frontal, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *hs* hiatus semilunaire, *pu* processus uncinatus, *be* bulle ethmoïdale, *mni* méat inférieur, *ci* cornet inférieur, *mm* méat moyen, *mns* méat supérieur.

Coupe sagittale d'une tête d'enfant de 5 mois ½ montrant le cornet inférieur (*ci*) sectionné, les méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*). La région de l'hiatus semilunaire (*hs*) est mise à nu avec la bulle ethmoïdale (*be*) environnante et le processus uncinatus (*pu*). Au-dessus on peut voir, d'avant en arrière, le sinus frontal (*sf*), les cellules ethmoïdales antérieure (*cea*) et postérieure (*cep*). La forme précoce du sinus frontal (*sf*) a 6½ millim. de long, 5½ millim. de haut, et 4 millim. de large; le sinus s'ouvre largement à la partie supérieure de l'hiatus semilunaire. La cellule ethmoïdale antérieure (*cea*) a de 3 à 6 millim. de haut, de 3½ à 4 millim. de large et de 2½ à 3 millim. de long. La cellule ethmoïdale postérieure (*cep*) a 5½ millim. de long, 5 millim. de haut et 4 millim. de large.

## Plate 38.

Natural size. — Child of 5½ months.

*sf* frontal sinus, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *hs* semilunar hiatus, *pu* uncinate process, *be* ethmoidal bulla, *mni* lower meatus, *ci* lower concha, *mm* middle meatus, *mns* upper meatus.

Longitudinal vertical section through the head of a child aged 5½ months, shewing the cut surface of the lower concha (*ci*), the lower (*mni*), middle (*mm*) and upper (*mns*) meatus. The region of the semilunar hiatus (*hs*) has been exposed; the hiatus is enclosed between the ethmoidal bulla (*be*) and the uncinate process (*pu*). Above the hiatus may be seen, from before backwards, the frontal sinus (*sf*), the anterior (*cea*) and posterior (*cep*) ethmoidal cells. The early form of the frontal sinus (*sf*) is 6½ mm long, 5½ mm high and 4 mm wide; it opens freely into the upper part of the semilunar hiatus (*hs*). The anterior ethmoidal cells (*cea*) are 3 to 6 mm high, 3½ to 4 mm wide and 2½ to 3 mm long. The posterior ethmoidal cell (*cep*) is 5½ mm long, 5 mm high and 4 mm wide.

Der Frontalschnitt des 12 Monate alten Kopfes ist etwas schräg geführt und zeigt die Stirnhöhle in ihrer frühen Form eines recessus frontalis (*rf*), welcher die Basis des Schuppenteiles des Stirnbeines erreicht und 6 mm hoch, 5 mm lang und 5 mm breit ist. Der recessus frontalis (*rf*) mündet oberhalb des hiatus semilunaris (*hs*), welchen die bulla ethmoidalis (*be*) und der processus uncinatus (*pu*) begrenzt. Ein Teil der mittleren (*cm*) und oberen (*cs*) Nasenmuschel ist entfernt worden um das Gebiet des hiatus semilunaris (*hs*) frei zu legen. Im Bereiche des mittleren Nasenganges und der unteren Nasenmuschel (*ci*) ist in einer Länge von 13 mm der Verlauf des ductus nasolacrimalis (*dnl*) zu sehen.

## Planche 52.

Grandeur nature. — Enfant de 12 mois.

*rf* recessus frontal. *pu* processus uncinatus. *be* lame de la bulle ethmoïdale. *hs* hiatus semilunaire. *ci* cornet inférieur. *mni* méat inférieur. *cm* cornet moyen. *mns* méat supérieur. *cs* cornet supérieur. *dnl* conduit nasolacrimal.

La coupe frontale d'une tête d'enfant de 12 mois est légèrement oblique et montre le sinus frontal dans la forme précoce d'un recessus frontal (*rf*), qui atteint la base de la squame de l'os frontal et est haut de 6 millim., long de 5 millim. et large de 5 millim. Le recessus frontal (*rf*) se termine au dessus de l'hiatus semilunaire (*hs*), qui est limité par la bulle ethmoïdale (*be*) et le processus uncinatus (*pu*). Une partie des cornets moyen (*cm*) et supérieur (*cs*) a été enlevée, pour libérer la région de l'hiatus semilunaire (*hs*). Au niveau du méat moyen et du cornet inférieur (*ci*) on peut voir le conduit nasolacrimal (*dnl*) sur une longueur de 13 millim.

## Plate 52.

Natural size. — Child of 12 months.

*rf* frontal recess. *pu* uncinate process. *be* lamina of ethmoidal bulla. *hs* semilunar hiatus. *ci* lower concha. *mni* lower meatus. *cm* middle concha. *mns* upper meatus. *cs* upper concha. *dnl* nasal duct.

Coronal section through the head of a child aged 12 months, cut in a slightly oblique direction, so as to shew the frontal sinus in an earlier stage of its development as frontal recess (*rf*); the sinus reaches the base of the squamous part of the frontal bone and is 6 mm high. 5 mm long and 5 mm wide. The opening of the frontal recess (*rf*) lies above the semilunar hiatus (*hs*) which is enclosed between the ethmoidal bulla (*be*) and the uncinate process (*pu*). Portions of the middle (*cm*) and upper (*cs*) conchae have been removed so as to expose the region of the semilunar hiatus (*hs*). Adjoining the middle meatus and the lower concha (*ci*) a portion, 13 mm long, of the nasal duct (*dnl*) can be seen.

## Tafel 53.

Natürliche Grösse. — 12 Monate altes Kind.

*sm* sinus maxillaris, *hs* hiatus semilunaris, *cep* cellula ethmoidalis posterior, *ci* concha inferior, *mni* meatus narium inferior, *cm* concha media, *mm* meatus narium medius, *cs* concha superior, *mns* meatus narium superior, *s* septum.

Der Frontalschnitt eines 12 Monate alten Kopfes zeigt die rechte Nasenhöhle, den Boden, das Dach, die innere und die äussere Wand der Nasenhöhle. An der äusseren Nasenhöhlenwand sind die untere (*ci*), die mittlere (*cm*) und die obere (*cs*) Nasenmuschel, der untere (*mni*), der mittlere (*mm*) und der obere (*mns*) Nasengang zu übersehen. Im mittleren Nasengang (*mm*) ist das hintere Ende des hiatus semilunaris (*hs*), im Bereiche des mittleren Nasenganges (*mm*) und der unteren Muschel (*ci*) die Kieferhöhle (*sm*) und im Bereiche des oberen Nasenganges (*mns*) die hinteren Siebbeinzellen (*cep*) zu sehen. Die Kieferhöhle (*sm*) ist 11 mm lang, 8 mm breit und 7 mm hoch. Die Siebbeinzellen haben eine Ausbreitung von 2—4 mm.

## Planche 53.

Grandeur nature. — Enfant de 12 mois.

*sm* sinus maxillaire, *hs* hiatus semilunaire, *cep* cellule ethmoïdale postérieure, *ci* cornet inférieur, *mni* méat inférieur, *cm* cornet moyen, *mm* méat moyen, *cs* cornet supérieur, *mns* méat supérieur, *s* septum.

La coupe frontale d'une tête d'un enfant de 12 mois montre la fosse nasale droite, le plancher, le toit, la paroi interne et externe de la fosse nasale. Sur la paroi externe de la fosse nasale on voit les cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*), les méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*). On peut voir dans le méat moyen (*mm*) la partie postérieure de l'hiatus semilunaire (*hs*), au niveau du méat moyen (*mm*) et du cornet inférieur (*ci*) le sinus maxillaire (*sm*) et au niveau du méat supérieur (*mns*) les cellules ethmoïdales postérieures (*cep*). Le sinus maxillaire (*sm*) est long de 11 millim., large de 8 millim. et haut de 7 millim. Les cellules ethmoïdales ont une étendue de 2 à 4 millim.

## Plate 53.

Natural size. — Child of 12 months.

*sm* maxillary antrum, *hs* semilunar hiatus, *cep* posterior ethmoidal cell, *ci* lower concha, *mni* lower meatus, *cm* middle concha, *mm* middle meatus, *cs* upper concha, *mns* upper meatus, *s* septum.

Coronal section through the head of a child aged 12 months, shewing the right nasal fossa, its floor, roof, mesial and lateral walls. In the lateral wall, the lower (*ci*), middle (*cm*), and upper (*cs*) concha, the lower (*mni*), middle (*mm*), and upper (*mns*) meatus are shewn. In the middle meatus (*mm*) the posterior extremity of the semilunar hiatus (*hs*) is visible; adjoining the middle meatus (*mm*) and lower concha (*ci*) is the maxillary antrum (*sm*), adjoining the upper meatus are the posterior ethmoidal cells (*cep*). The maxillary antrum (*sm*) is 11 mm long, 8 mm wide and 7 mm high. The diameter of the ethmoidal cells is between 2 and 4 mm.

## Tafel 54.

Natürliche Grösse. — 12 Monate altes Kind.

*rf* recessus frontalis, *cea* cellula ethmoidalis anterior, *be* bulla ethmoidalis, *cep* cellula ethmoidalis posterior, *pu* processus uncinatus, *hs* hiatus semilunaris, *ci* concha inferior, *mni* meatus narium inferior, *cm* concha media, *mm* meatus narium medius, *cs* concha superior, *mns* meatus narium superior, *s* septum.

Der Sagittalschnitt eines 12 Monate alten Kopfes zeigt einen kleinen recessus frontalis (*rf*) knapp ober dem vorderen Ende des hiatus semilunaris (*hs*), welchen der processus uncinatus (*pu*) und die bulla ethmoidalis (*be*) begrenzt. Im vorderen Teil des hiatus semilunaris (*hs*) mündet die vordere Siebbeinzelle (*cea*), die 9 mm lang, 8 mm hoch und 6 mm breit ist. Die bulla ethmoidalis (*be*) hat eine Ausdehnung von 3—4 mm. Die hintere Siebbeinzelle (*cep*) ist 8 mm breit, 5 mm lang und hoch. Der Schnitt zeigt ferner einen Teil der unteren (*ci*), mittleren (*cm*) und oberen (*cs*) Muschel, des unteren (*mni*), mittleren (*mm*) und oberen (*mns*) Nasenganges.

## Planche 54.

Grandeur nature. — Enfant de 12 mois.

*rf* recessus frontal, *cea* cellule ethmoïdale antérieure, *be* bulle ethmoïdale, *cep* cellule ethmoïdale postérieure, *pu* processus uncinatus, *hs* hiatus semilunaire, *ci* cornet inférieur, *mni* méat inférieur, *cm* cornet moyen, *mm* méat moyen, *cs* cornet supérieur, *mns* méat supérieur, *s* septum.

La coupe sagittale de la tête d'un enfant de 12 mois montre un petit recessus frontal (*rf*), juste à l'extrémité antérieure de l'hiatus semilunaire (*hs*), limité par le processus uncinatus (*pu*) et la bulle ethmoïdale (*be*). Dans la partie antérieure de l'hiatus semilunaire (*hs*) se termine la cellule ethmoïdale antérieure (*cea*), qui est longue de 9 millim., haute de 8 millim. et large de 6 millim. La bulle ethmoïdale (*be*) a une étendue de 3 à 4 millim. La cellule ethmoïdale postérieure (*cep*) a une largeur de 8 millim., une longueur et une hauteur de 5 millim. La coupe montre de plus une partie des cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*), des méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*).

## Plate 54.

Natural size. — Child of 12 months.

*rf* frontal recess, *cea* anterior ethmoidal cell, *be* ethmoidal bulla, *cep* posterior ethmoidal cell, *pu* uncinate process, *hs* semilunar hiatus, *ci* lower concha, *mni* lower meatus, *cm* middle concha, *mm* middle meatus, *cs* upper concha, *mns* upper meatus, *s* septum.

Longitudinal vertical section through the head of a child aged 12 months, shewing a small frontal recess (*rf*) situated immediately above the anterior extremity of the semilunar hiatus (*hs*) which is enclosed between the uncinate process (*pu*) and the ethmoidal bulla (*be*). In the anterior portion of the semilunar hiatus (*hs*) is the opening of the anterior ethmoidal cell (*cea*); this cell is 9 mm long, 8 mm high and 6 mm wide. The ethmoidal bulla (*be*) is 3 to 4 mm in size. The posterior ethmoidal cell (*cep*) is 8 mm in width, 5 mm in length and height. The section also shews parts of the lower (*ci*), middle (*cm*) and upper (*cs*) concha, and of the lower (*mni*), middle (*mm*) and upper (*mns*) meatus.

## Tafel 62.

Natürliche Grösse. — 15 Monate altes Kind.

*sf* sinus frontalis, *cea* cellula ethmoidalis anterior, *pu* processus uncinatus, *be* bulla ethmoidalis, *hs* hiatus semilunaris, *cep* cellula ethmoidalis posterior, *os* ostium sphenoidale, *mns* meatus narium superior, *nni* meatus narium inferior, *mm* meatus narium medius, *ci* concha inferior, *cm* concha media, *cs* concha superior.

Der Sagittalschnitt eines 15 Monate alten Kopfes zeigt den unteren (*nni*), mittleren (*mm*) und oberen (*mns*) Nasengang, die untere (*ci*), mittlere (*cm*) und obere (*cs*) Nasenmuschel, in der Reihenfolge von vorne nach hinten die Stirnhöhle (*sf*), die vordere Siebbeinzelle (*cea*), die hintere Siebbeinzelle (*cep*) und das ostium sphenoidale (*os*). Die Stirnhöhle (*sf*) ist 7 mm hoch, 5 mm lang und 4 mm breit, sie mündet am oberen vorderen Teile des hiatus semilunaris, welchen der processus uncinatus (*pu*) und die bulla ethmoidalis (*be*) begrenzt. Die vordere Siebbeinzellen (*cea*) sind 3 bis 4 mm lang,  $3\frac{1}{2}$ — $4\frac{1}{2}$  mm breit und 3— $4\frac{1}{2}$  mm hoch, eine vordere Siebbeinzelle (*cea*) setzt sich noch von der Schnittfläche 6 mm in den processus uncinatus (*pu*) fort. Die hintere Siebbeinzelle (*cep*) ist 6 mm lang, 5 mm hoch und 4 mm breit, ihre direkte Mündung in den oberen Nasengang (*mns*) ist zu übersehen. Das  $1\frac{1}{2}$  mm weite ostium sphenoidale (*os*) führt in die 5 mm lange,  $3\frac{1}{2}$  mm hohe und 3 mm breite Keilbeinhöhle.

## Planche 62.

Grandeur nature. — Enfant de 15 mois.

*sf* sinus frontal, *cea* cellule ethmoïdale antérieure, *pu* processus uncinatus, *be* bulle ethmoïdale, *cep* cellule ethmoïdale postérieure, *os* ostium du sinus sphénoïdal, *hs* hiatus semilunaire, *nni* méat inférieur, *mm* méat moyen, *mns* méat supérieur, *ci* cornet inférieur, *cm* cornet moyen, *cs* cornet supérieur.

Coupe sagittale d'une tête d'enfant de 15 mois montrant les méats inférieur (*nni*), moyen (*mm*) et supérieur (*mns*), les cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*). En allant d'avant en arrière, le sinus frontal (*sf*), la cellule ethmoïdale antérieure (*cea*), la cellule ethmoïdale postérieure (*cep*) et l'ostium du sinus sphénoïdal (*os*). Le sinus frontal (*sf*) a 7 millim. de haut, 5 millim. de long et 4 millim. de large; il s'ouvre à la partie antéro-supérieure de l'hiatus semilunaire, limité par le processus uncinatus (*pu*) et la bulle ethmoïdale (*be*). La cellule ethmoïdale antérieure a de 3 à 4 millim. de long, de  $3\frac{1}{2}$  à  $4\frac{1}{2}$  millim. de large et de 3 à  $4\frac{1}{2}$  millim. de haut. Une cellule ethmoïdale antérieure (*cea*) se continue encore sur une longueur de 6 millim. dans le processus uncinatus (*pu*). La cellule ethmoïdale postérieure (*cep*) a 6 millim. de long, 5 millim. de haut et 4 millim. de large; on peut voir son ostium juste dans le méat supérieur (*mns*). L'ostium du sinus sphénoïdal (*os*) large de  $\frac{1}{2}$  millim. conduit dans le sinus sphénoïdal long de 5 millim., haut de  $3\frac{1}{2}$  millim. et large de 3 millim.

## Plate 62.

Natural size. — Child of 15 months.

*sf* frontal sinus, *cea* anterior ethmoidal cell, *pu* uncinate process, *hs* semilunar hiatus, *be* ethmoidal bulla, *cep* posterior ethmoidal cell, *os* sphenoidal ostium, *nni* lower meatus, *mm* middle meatus, *mns* upper meatus, *ci* lower concha, *cm* middle concha, *cs* upper concha.

Longitudinal vertical section through the head of a child aged 15 months, shewing the lower (*nni*), middle (*mm*) and upper (*mns*) meatus, the lower (*ci*), middle (*cm*) and upper (*cs*) concha, and, from before backwards, the frontal sinus (*sf*), the anterior ethmoidal cells (*cea*), the posterior ethmoidal cell (*cep*) and the sphenoidal ostium (*os*). The frontal sinus (*sf*) is 7 mm high, 5 mm long and 4 mm wide; it opens into the anterior, upper portion of the semilunar hiatus which is enclosed between the uncinate process (*pu*) and the ethmoidal bulla (*be*). The anterior ethmoidal cells (*cea*) are 3 to 4 mm long,  $3\frac{1}{2}$  to  $4\frac{1}{2}$  mm wide and 3 to  $4\frac{1}{2}$  mm high; one anterior ethmoidal cell (*cea*) extends from the plane of section into the uncinate process (*pu*) for a distance of 6 mm. The posterior ethmoidal cell (*cep*) is 6 mm long, 5 mm high and 4 mm wide; its opening into the upper meatus (*mns*) can be seen. The sphenoidal ostium (*os*), an aperture  $1\frac{1}{2}$  mm in diameter, leads into the sphenoidal sinus which measures 5 mm in length,  $3\frac{1}{2}$  mm in height and 3 mm in width.

Natürliche Grösse. — 1½ Jahr altes Kind.

*ci* concha inferior, *mni* meatus narium inferior, *cm* concha media, *mm* meatus narium medius, *sm* sinus maxillaris, *ce* cellula ethmoidalis, *s* septum, *p* palatum, *d* Zahnanlage, *pu* processus uncinatus.

Der Frontalschnitt eines 1½ Jahre alten Kopfes zeigt die in der Medianlinie geradverlaufende Nasensecheidewand (*s*), an der lateralen Nasenhöhlenwand die untere (*ci*) und mittlere (*cm*) Nasenmuschel, den unteren (*mni*) und den mittleren Nasengang (*mm*), den Boden und das Dach der Nasenhöhle, ferner die Kieferhöhle (*sm*), die Siebbeinzelle (*ce*) und Zahnkeime (*d*). Die Kieferhöhle (*sm*) hat eine Ausdehnung von 10 mm Länge, 8 mm Höhe und 3 mm Breite. Auf der rechten Seite ist die Mündung der Kieferhöhle (*sm*) in den hiatus semilunaris zu übersehen, begrenzt vom processus uncinatus (*pu*). Die rechte Siebbeinzelle (*ce*) ist 6 mm lang, 5 mm hoch und 3 mm breit, die linke Siebbeinzelle (*ce*) ist 4 mm lang, 4 mm hoch und 1½ mm breit.

## Planche 64.

Grandeur nature. — Enfant de 1 an ½.

*ci* cornet inférieur, *mni* méat inférieur, *cm* cornet moyen, *mm* méat moyen, *sm* sinus maxillaire, *ce* cellule ethmoïdale, *s* septum, *p* palais, *d* couche dentaire, *pu* processus uncinatus.

La coupe frontale d'une tête d'enfant de 1 an ½ présente un septum (*s*) tout droit dans la ligne médiane. Sur la paroi latérale de la fosse nasale on voit les cornets inférieur (*ci*) et moyen (*cm*), les méats inférieur (*mni*) et moyen (*mm*), le plancher et le toit de la fosse nasale, de plus le sinus maxillaire (*sm*), la cellule ethmoïdale (*ce*) et la couche dentaire (*d*). Le sinus maxillaire (*sm*) est long de 10 millim., haut de 8 millim. et large de 3 millim. On voit sur le côté droit l'ostium du sinus maxillaire donnant dans le hiatus semilunaire, convert par le processus uncinatus (*pu*). La cellule ethmoïdale droite (*ce*) est longue de 6 millim., haute de 5 millim. et large de 3 millim. Les dimensions correspondantes de la cellule ethmoïdale gauche (*ce*) sont 4 millim., 4 millim. et 1½ millim.

## Plate 64.

Natural size. — Child of 1½ years.

*ci* lower concha, *mni* lower meatus, *cm* middle concha, *mm* middle meatus, *sm* maxillary antrum, *ce* ethmoidal cell, *s* septum, *p* hard palate, *d* dental germ, *pu* uncinate process.

Coronal section through the head of a child aged 1½ years, shewing the nasal septum (*s*) situated in the median plane, and in the lateral wall of each nasal fossa, the lower (*ci*) and middle (*cm*) concha, the lower (*mni*) and middle (*mm*) meatus, also the floor and roof of the nasal fossae, the maxillary antrum (*sm*), ethmoidal cell (*ce*) and dental germs (*d*). The maxillary antrum (*sm*) is 10 mm long, 8 mm high, and 3 mm wide. On the right hand side, the opening of the maxillary antrum (*sm*) into the semilunar hiatus may be seen. This orifice is bounded by the uncinate process (*pu*). The right ethmoidal cell (*ce*) is 6 mm long, 5 mm high, and 3 mm wide; the left ethmoidal cell (*ce*) is 4 mm long, 4 mm high, and 1½ mm wide.

*sf* sinus frontalis, *cea* cellula ethmoidalis anterior, *hs* hiatus semilunaris, *be* bulla ethmoidalis, *pu* processus uncinatus, *cs* concha superior, *mns* meatus narium superior, *cm* concha media, *mm* meatus narium medius, *ci* concha inferior, *mni* meatus narium inferior.

Der Frontalschnitt eines 2 Jahre alten Kopfes zeigt den unteren (*mni*), mittleren (*mm*) und den oberen (*mns*) Nasengang, die untere (*ci*); mittlere (*cm*) und obere (*cs*) Nasenmuschel. Im Gebiete des hiatus semilunaris (*hs*), welchen der processus uncinatus (*pu*) und die bulla ethmoidalis (*be*) begrenzt, ist die Stirnhöhle (*sf*) und die vordere Siebbeinzelle (*cea*) zu sehen. Die Stirnhöhle (*sf*) ist  $5\frac{1}{2}$  mm hoch, 4 mm breit und 3 mm lang, sie mündet am vorderen oberen Ende des hiatus semilunaris (*hs*). Die vordere Siebbeinzelle (*cea*) ist 5 mm hoch, 4 mm breit und  $3\frac{1}{2}$  mm lang, diese Zelle reicht von der Schnittfläche noch 10 mm in den processus uncinatus (*pu*).

## Planche 69.

Grandeur nature. — Enfant de 2 ans.

*sf* sinus frontal, *cea* cellule ethmoïdale antérieure, *hs* hiatus semilunaire, *be* bulle ethmoïdale, *pu* processus uncinatus, *cs* cornet supérieur, *mns* méat supérieur, *cm* cornet moyen, *mm* méat moyen, *ci* cornet inférieur, *mni* méat inférieur.

Coupe frontale d'une tête de 2 ans montrant les méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*), les cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*). Dans la région de l'hiatus semilunaire (*hs*), qui est limitée par le processus uncinatus (*pu*) et la bulle ethmoïdale (*be*) on peut voir le sinus frontal (*sf*) et la cellule ethmoïdale antérieure. Le sinus frontal (*sf*) a  $5\frac{1}{2}$  millim. de haut, 4 millim. de large et 3 millim. de long; il s'ouvre à l'extrémité antéro-supérieure de l'hiatus semilunaire (*hs*). La cellule ethmoïdale antérieure (*cea*) a 5 millim. de haut, 4 millim. de large et  $3\frac{1}{2}$  millim. de long. Cette cellule s'étend depuis le plan de la section encore 10 millim. dans le processus uncinatus (*pu*).

## Plate 69.

Natural size. — Child of 2 years.

*sf* frontal sinus, *cea* anterior ethmoidal cell, *hs* semilunar hiatus, *be* ethmoidal bulla, *pu* uncinate process, *cs* upper concha, *mns* upper meatus, *cm* middle concha, *mm* middle meatus, *ci* lower concha, *mni* lower meatus.

Coronal section through the head of a child aged 2 years, shewing the lower (*mni*), middle (*mm*) and upper (*mns*) meatus, and the lower (*ci*) middle (*cm*) and upper (*cs*) concha. The semilunar hiatus (*hs*) may be seen enclosed between the uncinate process (*pu*) and the ethmoidal bulla (*be*) and adjoining it, the frontal sinus (*sf*) and the anterior ethmoidal cell (*cea*). The frontal sinus (*sf*) is  $5\frac{1}{2}$  mm high, 4 mm wide and 3 mm long; it opens at the upper anterior extremity of the semilunar hiatus (*hs*). The anterior ethmoidal cell (*cea*) is 5 mm high, 4 mm wide and  $3\frac{1}{2}$  mm long. This cell extends into the uncinate process (*pu*) for a distance of 10 mm below the plane of the section.

## Tafel 72.

Natürliche Grösse. — 2 Jahre altes Kind.

*sf* sinus frontalis, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *os* ostium sphenoidale, *ss* sinus sphenoidalis, *hs* hiatus semilunaris, *be* bulla ethmoidalis, *pu* processus uncinatus, *mni* meatus narium inferior, *ci* concha inferior, *mm* meatus narium medius, *cm* concha media, *mns* meatus narium superior, *cs* concha superior.

Der Sagittalschnitt eines 2 Jahre alten Kopfes zeigt die äussere Wand der Nasenhöhle, den unteren (*mni*), mittleren (*mm*) und den oberen (*mns*) Nasengang, die untere (*ci*), die mittlere (*cm*) und die obere (*cs*) Nasenmuschel. Durch den weggefallenen Teil der mittleren Muschel (*cm*) ist das Gebiet des hiatus semilunaris (*hs*) freigelegt, den hiatus semilunaris (*hs*) begrenzt die bulla ethmoidalis (*be*) und der processus uncinatus (*pu*). In der Reihenfolge von vorne nach hinten ist die Stirnhöhle (*sf*), die vordere Siebbeinzelle (*cea*), die hintere Siebbeinzelle (*cep*) und die Keilbeinhöhle (*ss*) in ihrer Lage und Ausbreitung zu sehen. Die Stirnhöhle (*sf*) ist  $7\frac{1}{2}$  mm hoch,  $5\frac{1}{2}$  mm lang und 3 mm breit, sie mündet am Dache des hiatus semilunaris (*hs*). Die vordere Siebbeinzelle (*cea*) ist  $4\frac{1}{2}$  mm lang, 5 mm hoch und  $3\frac{1}{2}$  mm breit. Die hintere Siebbeinzelle ist 4 mm lang, 5 mm hoch und 3 mm breit. Die Keilbeinhöhle (*ss*) ist  $6\frac{1}{2}$  mm breit, 4 mm hoch und  $4\frac{1}{2}$  mm lang. Das ostium sphenoidale ist 1 mm weit.

## Planche 72.

Grandeur nature. Enfant de 2 ans.

*sf* sinus frontal, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *os* ostium du sinus sphénoïdal, *ss* sinus sphénoïdal, *hs* hiatus semilunaire, *be* bulle ethmoïdale, *pu* processus uncinatus, *mni* méat inférieur, *ci* cornet inférieur, *mm* méat moyen, *cm* cornet moyen, *mns* méat supérieur, *cs* cornet supérieur.

Coupe sagittale d'une tête de 2 ans montrant la paroi latérale de la fosse nasale, les méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*), les cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*). Par l'ablation d'une partie du cornet moyen (*cm*) la région de l'hiatus semilunaire (*hs*) est mise à nu; l'hiatus semilunaire (*hs*) est limité par la bulle ethmoïdale (*be*) et le processus uncinatus (*pu*). En allant d'en avant en arrière on peut voir le sinus frontal (*sf*), la cellule ethmoïdale antérieure (*cea*), la cellule ethmoïdale postérieure (*cep*) et le sinus sphénoïdal. Le sinus frontal (*sf*) a une hauteur de  $7\frac{1}{2}$  millim., une longueur de  $5\frac{1}{2}$  millim. et une largeur de 3 millim., il s'ouvre au toit de l'hiatus semilunaire (*hs*). La cellule ethmoïdale antérieure (*cea*) a  $4\frac{1}{2}$  millim. de long, 5 millim. de haut et  $3\frac{1}{2}$  millim. de large. La cellule ethmoïdale postérieure a 4 millim. de long, 5 millim. de haut et 3 millim. de large. Le sinus sphénoïdal (*ss*) a  $6\frac{1}{2}$  millim. de large, 4 millim. de haut.  $4\frac{1}{2}$  millim. de long. Son ostium a 1 millim. de large.

## Plate 72.

Natural size. — Child of 2 years.

*sf* frontal sinus, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *os* sphenoidal ostium, *ss* sphenoidal sinus, *hs* semilunar hiatus, *be* ethmoidal bulla, *pu* uncinat process, *mni* lower meatus, *ci* lower concha, *mm* middle meatus, *cm* middle concha, *mns* upper meatus, *cs* upper concha.

Longitudinal vertical section through the head of a child aged 2 years, shewing the lateral wall of the nasal fossa, the lower (*mni*), middle (*mm*) and upper (*mns*) meatus, and the lower (*ci*), middle (*cm*) and upper (*cs*) concha. Through the removal of part of the middle concha (*cm*), the region of the semilunar hiatus (*hs*) has been exposed; the semilunar hiatus (*hs*) is enclosed between the ethmoidal bulla (*be*) and the uncinat process (*pu*). From before backwards may be seen in their full extent the frontal sinus (*sf*), the anterior (*cea*) and posterior (*cep*) ethmoidal cell and the sphenoidal sinus (*ss*). The frontal sinus (*sf*) is  $7\frac{1}{2}$  mm high,  $5\frac{1}{2}$  mm long and 3 mm wide; it opens into the roof of the semilunar hiatus (*hs*). The anterior ethmoidal cell (*cea*) is  $4\frac{1}{2}$  mm long, 5 mm high and  $3\frac{1}{2}$  mm wide. The posterior ethmoidal cell (*cep*) is 4 mm long, 5 mm high and 3 mm wide. The sphenoidal sinus (*ss*) is  $6\frac{1}{2}$  mm wide, 4 mm high and  $4\frac{1}{2}$  mm long. The sphenoidal ostium (*os*) is 1 mm wide.

## Tafel 73.

Natürliche Grösse. — 3 Jahre altes Kind.

*sf* sinus frontalis, *of* ostium frontale, *hs* hiatus semilunaris, *pu* processus uncinatus, *be* bulla ethmoidalis, *cm* concha media, *mm* meatus narium medius, *ci* concha inferior, *mni* meatus narium inferior, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *cs* concha superior, *mns* meatus narium superior, *ss* sinus sphenoidalis.

Der Sagittalschnitt eines 3 Jahre alten Kopfes zeigt die Nasenhöhle und die Nebenhöhlen von innen eröffnet. Die untere Nasenmuschel (*ci*) ist ganz erhalten, die mittlere (*cm*) und die obere (*cs*) Nasenmuschel ist zum Teil weggefallen, unter den Muscheln ist der untere (*mni*), der mittlere (*mm*) und der obere (*mns*) Nasengang zu übersehen. Durch den Wegfall eines Teiles der mittleren Muschel (*cm*) ist das Gebiet des hiatus semilunaris (*hs*) freigelegt, welcher oben von der bulla ethmoidalis (*be*), unten vom processus uncinatus (*pu*) begrenzt ist. Die rechte Stirnhöhle (*sf*) ist 11 mm lang, 14 mm hoch und 5 mm breit, sie mündet mit einer  $2\frac{1}{2}$  mm länglich ovalen Öffnung (*of*) am vordersten Ende des hiatus semilunaris (*hs*). Der oberste Teil der Stirnhöhle (*sf*) erstreckt sich im unteren Schuppenteile des Stirnbeines. Die vorderen (*cea*) und die hinteren (*cep*) Siebbeinzellen sind 6—7 mm lang und hoch, 3—4 mm breit. Die Mündung einer hinteren Siebbeinzelle (*cep*) in den oberen Nasengang (*mns*), ferner die Mündung der Keilbeinhöhle (*ss*) und ihre Ausbreitung im Keilbeinkörper ist gut zu übersehen. Die rechte Keilbeinhöhle (*ss*) ist 9 mm breit, 6 mm lang und 6 mm hoch, das ostium sphenoidale ist 2 mm weit.

## Planche 73.

Grandeur nature. — Enfant de 3 ans.

*sf* sinus frontal, *of* ostium du sinus frontal, *hs* hiatus semilunaire, *pu* processus uncinatus, *be* bulle ethmoïdale, *cm* cornet moyen, *mm* méat moyen, *ci* cornet inférieur, *mni* méat inférieur, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *cs* cornet supérieur, *mns* méat supérieur, *ss* sinus sphénoïdal.

Coupe sagittale de la tête d'un enfant de 3 ans montrant la fosse nasale et les sinus ouverts. Le cornet inférieur (*ci*) est complètement conservé, les cornets moyen (*cm*) et supérieur (*cs*) sont en partie enlevés. Au dessous des cornets on voit les trois méats: le méat inférieur (*mni*), le méat moyen (*mm*) le méat supérieur (*mns*). Par la section d'une partie du cornet moyen (*cm*) la région de l'hiatus semilunaire est devenue visible, limitée en haut par la bulle ethmoïdale et en bas par le processus uncinatus. Le sinus frontal droit (*sf*) est long de 11 millim. haut de 14 millim. et large de 5 millim. Son orifice (*of*) long de  $2\frac{1}{2}$  millim. se trouve à la partie la plus avancée de l'hiatus semilunaire (*hs*). La partie la plus haute du sinus frontal (*sf*) se trouve dans la partie inférieure de la squame de l'os frontal. Les cellules ethmoïdales antérieures (*cea*) et postérieures (*cep*) sont longues de 6 à 7 millim. et larges de 3 à 4 millim. On voit distinctement l'ouverture d'une cellule ethmoïdale postérieure (*cep*) dans le méat supérieur (*mns*) et l'ouverture du sinus sphénoïdal (*ss*) et son développement dans l'os sphénoïdal. Le sinus sphénoïdal droit (*ss*) est large de 9 millim., haut de 6 millim. long de 6 millim. L'ostium sphénoïdal a 2 millim. de largeur.

## Plate 73.

Natural size. — Child of 3 years.

*sf* frontal sinus, *of* frontal ostium, *hs* semilunar hiatus, *pu* uncinat process, *be* ethmoidal bulla, *cm* middle concha, *mm* middle meatus, *ci* lower concha, *mni* lower meatus, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *cs* upper concha, *mns* upper meatus, *ss* sphenoidal sinus.

Longitudinal vertical section through the head of a child aged 3 years, shewing the nasal fossa and accessory sinuses which have been opened up from their mesial surface. The lower concha (*ci*) has been preserved, but parts of the middle (*cm*) and upper (*cs*) conchae have been removed: below the conchae the lower (*mni*), middle (*mm*), and upper (*mns*) meatus are seen. By the removal of part of the middle concha (*cm*) the region of the semilunar hiatus (*hs*) has been exposed; it is bounded above by the ethmoidal bulla (*be*), below by the uncinat process (*pu*). The right frontal sinus (*sf*) is 11 mm long, 14 mm high, and 5 mm wide; it communicates by an elongated oval opening (*of*)  $2\frac{1}{2}$  mm wide with the anterior part of the semilunar hiatus (*hs*). The upper part of the frontal sinus (*sf*) extends into the lower squamous portion of the frontal bone. The anterior (*cea*) and posterior (*cep*) ethmoidal cells are 6 to 7 mm in length and in height, 3 to 4 mm in width. The opening of a posterior ethmoidal cell (*cep*) into the upper meatus (*mns*), the orifice of the sphenoidal sinus (*ss*), and the situation of this sinus in the body of the sphenoid bone are clearly visible. The right sphenoidal sinus (*ss*) is 9 mm wide, 6 mm long and 6 mm high; the sphenoidal ostium is 2 mm in diameter.

## Tafel 74.

Natürliche Grösse. — 3 Jahre altes Kind.

*sf* sinus frontalis, *cm* concha media, *mnm* meatus narium medius, *cea* cellula ethmoidalis anterior, *cs* concha superior, *mns* meatus narium superior, *cep* cellula ethmoidalis posterior, *ss* sinus sphenoidalis, *os* ostium sphenoidale.

Der Sagittalschnitt eines 3 Jahre alten Kopfes stellt den korrespondierenden Schnitt der Tafel 73 dar. Man sieht den von der mittleren Nasenmuschel (*cm*) bedeckten vordersten Teil des mittleren Nasenganges (*mnm*) und in demselben einen streifenartigen Teil der Lamelle der bulla ethmoidalis. Ganz vorne oben ist ein kleiner Teil der Stirnhöhle (*sf*) zu sehen, hinter ihr liegt eine vordere Siebbeinzelle (*cea*), welche direkt im recessus bullaris mündet, welcher in der Tafel deutlich ausgeprägt erscheint, dann folgen zwei hintere Siebbeinzellen (*cep*). eine mündet direkt breit im oberen Nasengang (*mns*). Im Körper des Keilbeines ist die Keilbeinhöhle (*ss*) mit ihrer Mündung, das ostium sphenoidale (*os*) zu übersehen. Die Maasse der Nebenhöhlen sind in der Tafel 73 erwähnt.

## Planche 74.

Grandeur nature. — Enfant de 3 ans.

*sf* sinus frontal, *cm* cornet moyen, *mnm* méat moyen, *cea* cellule ethmoïdale antérieure, *cs* cornet supérieur, *mns* méat supérieur, *cep* cellule ethmoïdale postérieure, *ss* sinus sphénoïdal, *os* ostium du sinus sphénoïdal.

Coupe sagittale d'une tête d'un enfant de 3 ans correspond à la coupe de la planche 73. On voit la partie antérieure du méat moyen (*mnm*) recouverte par le cornet moyen (*cm*), et dans ce méat une partie de la lame de la bulle ethmoïdale. Tout à fait en avant et en haut on voit encore une petite partie du sinus frontal (*sf*). Derrière le sinus se trouve une cellule ethmoïdale antérieure (*cea*) qui s'ouvre directement dans le recessus bullaris très marqué sur la planche. Suivent ensuite deux cellules ethmoïdales postérieures (*cep*), dont une s'ouvre directement dans le méat nasal supérieur (*mns*). Dans le corps de l'os sphénoïdal on voit le sinus sphénoïdal (*ss*) avec son orifice (*os*). Les mesures des sinus sont mentionnées sur la planche 73.

## Plate 74.

Natural size. — Child of 3 years.

*sf* frontal sinus, *cm* middle concha, *mnm* middle meatus, *cea* anterior ethmoidal cell, *cs* upper concha, *mns* upper meatus, *cep* posterior ethmoidal cell, *ss* sphenoidal sinus, *os* sphenoidal ostium.

This section, a longitudinal vertical section through the head of a child aged 3 years, corresponds to the one figured on Plate 73. The anterior portion of the middle meatus (*mnm*) is shewn, overhung by the middle concha (*cm*); in the meatus a narrow strip of the lamina of the ethmoidal bulla is visible. At the upper anterior extremity of the nasal fossa a small part of the frontal sinus (*sf*) may be recognised; behind this is an anterior ethmoidal cell (*cea*) which communicates freely with the well-marked bullar recess; still further backwards are two posterior ethmoidal cells (*cep*), one of which opens directly into the upper meatus (*mns*). Within the body of the sphenoid bone lies the sphenoidal sinus (*ss*) with its orifice, the sphenoidal ostium (*os*). The measurements of the sinuses are given in the description of Plate 73.

*sf* sinus frontalis, *cea* cellula ethmoidalis anterior, *hs* hiatus semilunaris, *be* bulla ethmoidalis, *pu* processus uncinatus, *dnl* ductus nasolacrimalis, *ci* concha inferior, *mni* meatus narium inferior.

Der Frontalschnitt eines 3 Jahre alten Kopfes hat den vorderen Teil der Stirnhöhle (*sf*) vor dem hiatus semilunaris (*hs*) getroffen. Die linke Stirnhöhle (*sf*) ist 6 mm breit, 16 mm lang und 18 mm hoch, sie mündet mit einer  $2\frac{1}{2}$  mm länglich ovalen Öffnung am obersten Teile des hiatus semilunaris, welcher von der bulla ethmoidalis (*be*) und vom processus uncinatus (*pu*) begrenzt ist. Die unterhalb der Stirnhöhle (*sf*) sichtbare vordere Siebbeinzelle (*cea*) erstreckt sich 7 mm weit in den processus uncinatus (*pu*). Nahe dem Gebiete des mittleren Nasenganges ist in einer Länge von 10 mm der ductus nasolacrimalis (*dnl*) zu sehen.

## Planche 75.

Grandeur nature. — Enfant de 3 ans.

*sf* sinus frontal, *cea* cellule ethmoïdale antérieure, *hs* hiatus semilunaire, *be* bulle ethmoïdale, *pu* processus uncinatus, *dnl* conduit nasolacrimal, *ci* cornet inférieur, *mni* méat inférieur.

Coupe frontale de la tête d'un enfant de 3 ans, passant par la partie antérieure du sinus frontal (*sf*) au-devant de l'hiatus semilunaire (*hs*). Le sinus frontal gauche (*sf*) est large de 6 millim. long de 16 millim. et haut de 18 millim. Le sinus s'ouvre par un orifice ovalaire de  $2\frac{1}{2}$  millim. de long dans la partie supérieure de l'hiatus semilunaire, qui est limitée par la bulle ethmoïdale (*be*) et le processus uncinatus (*pu*). Au-dessus du sinus frontal (*sf*) on voit une cellule ethmoïdale antérieure (*cea*), qui, sur une longueur de 7 millim., avance dans le processus uncinatus (*pu*). Près du méat moyen le conduit nasolacrimal (*dnl*) est ouvert sur une longueur de 10 millim.

## Plate 75.

Grandeur nature. — Enfant de 3 ans.

*ci* cornet inférieur, *mni* méat inférieur, *sm* sinus maxillaire, *cm* cornet moyen, *mm* méat moyen, *cs* cornet supérieur, *mns* méat supérieur, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure.

Coupe frontale d'une tête de 3 ans montrant la paroi latérale de la fosse nasale avec les méats inférieur (*mni*), moyen (*mm*), supérieur (*mns*) et les cornets inférieur (*ci*), moyen (*cm*), supérieur (*cs*). On voit sur la coupe les cellules ethmoïdales antérieures (*cea*) et postérieures (*cep*) et le sinus maxillaire (*sm*). Le sinus maxillaire gauche (*sm*) est haut de 13 millim., large de 13 millim. et long de 23 millim. Il s'ouvre dans la partie postérieure de l'hiatus semilunaire.

## Plate 76.

Natural size. — Child of 3 years.

*ci* lower concha, *mni* lower meatus, *sm* maxillary antrum, *cm* middle concha, *mm* middle meatus, *cs* upper concha, *mns* upper meatus, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell.

Coronal section through the head of a child aged 3 years, shewing the lateral wall of the nasal fossa, with the lower (*mni*) middle (*mm*), and upper (*mns*) meatus, and the lower (*ci*), middle (*cm*), and upper (*cs*) concha. The section has opened up the anterior (*cea*) and posterior (*cep*) ethmoidal cells and the maxillary antrum (*sm*). The left maxillary antrum (*sm*) is 23 mm long, 13 mm wide, and 13 mm high. It opens into the posterior portion of the semilunar hiatus.

## Tafel 78.

Natürliche Grösse. —  $3\frac{1}{2}$  Jahre altes Kind.

*sf* sinus frontalis, *rf* recessus frontalis, *of* ostium frontale, *hs* hiatus semilunaris, *pu* processus uncinatus, *cea* cellula ethmoidalis anterior, *ci* concha inferior, *cm* concha media, *mns* meatus narium superior, *cs* concha superior.

Der Frontalschnitt des  $3\frac{1}{2}$  Jahre alten Kopfes ist etwas schräg geführt und zeigt das freigelegte Gebiet des hiatus semilunaris (*hs*), begrenzt vom processus uncinatus (*pu*), die durchschnittenen Teile der unteren (*ci*), mittleren (*cm*) und der oberen (*cs*) Nasenmuschel, einen Teil des unteren, mittleren und oberen (*mns*) Nasenganges, die Stirnhöhle (*sf*) und die vordere Siebbeinzelle (*cea*). Oberhalb des hiatus semilunaris (*hs*) ist der schmale recessus frontalis (*rf*) zu sehen, wo die Stirnhöhle mit einer länglich ovalen Öffnung (*of*) mündet. Die Stirnhöhle (*sf*) ist 6 mm lang,  $6\frac{1}{2}$  mm hoch und 5 mm breit. Die vordere Siebbeinzelle (*cea*) ist 8 mm lang, 6 mm hoch und 4 mm breit und erstreckt sich in den processus uncinatus (*pu*).

## Planche 78.

Grandeur nature. — Enfant de 3 ans  $\frac{1}{2}$ .

*sf* sinus frontal, *rf* recessus frontal, *of* ostium du sinus frontal, *hs* hiatus semilunaire, *pu* processus uncinatus, *cea* cellule ethmoïdale antérieure, *ci* cornet inférieur, *cm* cornet moyen, *mns* méat supérieur, *cs* cornet supérieur.

Coupe frontale d'une tête de 3 ans  $\frac{1}{2}$ , légèrement oblique et montrant la région mise à nu de l'hiatus semilunaire (*hs*), limitée par le processus uncinatus (*pu*), la partie sectionnée des cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*), une partie des méats inférieur, moyen et supérieur (*mns*), le sinus frontal et la cellule ethmoïdale antérieure (*cea*). Au-dessus de l'hiatus semilunaire (*hs*) on peut voir l'étroit recessus frontal (*rf*) ou s'ouvre le sinus frontal par un ostium ovalaire allongé (*of*). Le sinus frontal a 6 millim. de long,  $6\frac{1}{2}$  millim. de haut et 5 millim. de large. La cellule ethmoïdale antérieure (*cea*) a 8 millim. de long, 6 millim. de haut et 4 millim. de large; elle s'étend jusque dans le processus uncinatus (*pu*).

## Plate 78.

Natural size. — Child of  $3\frac{1}{2}$  years.

*sf* frontal sinus, *rf* frontal recess, *of* frontal ostium, *hs* semilunar hiatus, *pu* uncinate process, *cea* anterior ethmoidal cell, *ci* lower concha, *cm* middle concha, *mns* upper meatus, *cs* upper concha.

Section through the head of a child aged  $3\frac{1}{2}$  years, cut in a plane slightly oblique to the coronal. The section shews the region of the semilunar hiatus (*hs*), bounded by the uncinate process (*pu*), the cut surfaces of the lower (*ci*), middle (*cm*) and upper (*cs*) conchae, part of the lower, middle and upper (*mns*) meatus, the frontal sinus (*sf*) and anterior ethmoidal cell (*cea*). Above the semilunar hiatus (*hs*) the narrow frontal recess (*rf*) is visible, together with the elongated oval aperture (*of*) of the frontal sinus. The frontal sinus (*sf*) is 6 mm long,  $6\frac{1}{2}$  mm high and 5 mm wide. The anterior ethmoidal cell (*cea*) is 8 mm long, 6 mm high and 4 mm wide, and extends into the uncinate process (*pu*).

## Tafel 80.

Natürliche Grösse. —  $3\frac{1}{2}$  Jahre altes Kind.

*sm* sinus maxillaris, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *os* ostium sphenoidale, *mni* meatus narium inferior, *ci* concha inferior, *mm* meatus narium medius, *cm* concha media, *mns* meatus narium superior, *cs* concha superior.

Der Frontalschnitt des  $3\frac{1}{2}$  Jahre alten Kopfes zeigt die laterale Wand der Nasenhöhle, den unteren (*mni*), den mittleren (*mm*) und den oberen (*mns*) Nasengang, die untere (*ci*), mittlere (*cm*) und die obere (*cs*) Nasenmuschel, die Kieferhöhle (*sm*), die vorderen (*cea*) und hinteren (*cep*) Siebbeinzellen und das ostium sphenoidale (*os*). Im Bereiche des unteren (*mni*) und mittleren (*mm*) Nasenganges ist der hintere Teil der Kieferhöhle (*sm*) sichtbar. Die vorderen Siebbeinzellen (*cea*) sind 6—8 mm lang,  $3\frac{1}{2}$ —5 mm hoch und 3—4 mm breit. Die hinteren Siebbeinzellen (*cep*) sind 6—11 mm lang, 5—6 mm hoch und  $3\frac{1}{2}$ —4 mm breit. In der Höhe des oberen Nasenganges (*mns*) ist das  $\frac{1}{2}$  mm weite ostium sphenoidale (*os*) zu sehen, welches in die 7 mm breite, 6 mm hohe und 5 mm lange Keilbeinhöhle führt.

## Planche 80.

Grandeur nature. — Enfant de 3 ans  $\frac{1}{2}$ .

*sm* sinus maxillaire, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *os* ostium du sinus sphénoïdal, *mni* méat inférieur, *ci* cornet inférieur, *mm* méat moyen, *cm* cornet moyen, *mns* méat supérieur, *cs* cornet supérieur.

Coupe frontale d'une tête de 3 ans  $\frac{1}{2}$  montrant la paroi latérale de la fosse nasale, les méats inférieur (*mni*), moyen (*mm*) et supérieur (*mns*), les cornets inférieur (*ci*), moyen (*cm*) et supérieur (*cs*), le sinus maxillaire (*sm*), les cellules ethmoïdales antérieures (*cea*) et postérieures (*cep*) et l'ostium du sinus sphénoïdal (*os*). Au niveau des méats inférieur (*mni*) et moyen (*mm*) la partie postérieure du sinus maxillaire (*sm*) est visible. Les cellules ethmoïdales antérieures (*cea*) ont de 6 à 8 millim. de long, de  $3\frac{1}{2}$  à 5 millim. de haut et de 3 à 4 millim. de large. Les cellules ethmoïdales postérieures (*cep*) ont de 6 à 11 millim. de long, de 5 à 6 millim. de haut et de  $3\frac{1}{2}$  à 4 millim. de large. Au niveau du méat supérieur (*mns*) on peut voir l'ostium du sinus sphénoïdal large de  $\frac{1}{2}$  millim. (*os*), qui conduit dans le sinus sphénoïdal large de 7 millim. haut de 6 millim. et long de 5 millim.

## Plate 80.

Natural size. — Child of  $3\frac{1}{2}$  years.

*sm* maxillary antrum, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *os* sphenoidal ostium, *mni* lower meatus, *ci* lower concha, *mm* middle meatus, *cm* middle concha, *mns* upper meatus, *cs* upper concha.

Coronal section through the head of a child aged  $3\frac{1}{2}$  years, shewing the lateral wall of the nasal fossa, the lower (*mni*), middle (*mm*) and upper (*mns*) meatus, the lower (*ci*), middle (*cm*) and upper (*cs*) concha, the maxillary antrum (*sm*), anterior (*cea*) and posterior (*cep*) ethmoidal cells and sphenoidal ostium (*os*). Adjoining the lower (*mni*) and middle meatus (*mm*) the back part of the maxillary antrum (*sm*) is visible. The anterior ethmoidal cells (*cea*) are 6 to 8 mm long,  $3\frac{1}{2}$  to 5 mm high and 3 to 4 mm wide. The posterior ethmoidal cells (*cep*) are 6 to 11 mm long, 5 to 6 mm high and  $3\frac{1}{2}$  to 4 mm wide. On a level with the upper meatus (*mns*) can be seen the sphenoidal ostium (*os*), an aperture  $\frac{1}{2}$  mm wide; it leads into the sphenoidal sinus, which is 7 mm wide, 6 mm high and 5 mm long.

Natürliche Grösse. —  $3\frac{1}{2}$  Jahre altes Kind

*rf* sinus frontalis, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *hs* hiatus semilunaris, *pu* processus uncinatus, *os* ostium sphenoidale, *ss* sinus sphenoidalis, *cm* concha media, *mm* meatus narium medius, *mns* meatus narium superior.

Der Sagittalschnitt des  $3\frac{1}{2}$  Jahre alten Kopfes zeigt den 7 mm hohen, 5 mm langen und 4 mm breiten recessus frontalis (*rf*), welcher mit seinem weiten unteren Teil vor dem hiatus semilunaris (*hs*) liegt, begrenzt von dem processus uncinatus (*pu*) und den vorderen Siebbeinzellen (*cea*). Am Schnitte ist die verschieden grosse Ausbreitung der einzelnen Siebbeinzellen, die kleine Keilbeinhöhle (*ss*), die mittlere (*cm*) Muschel, der mittlere (*mm*) und der obere (*mns*) Nasengang zu sehen. Die vorderen Siebbeinzellen (*cea*) sind 5—11 mm hoch,  $3\frac{1}{2}$ —7 mm breit und 3—6 mm lang. Die hinteren Siebbeinzellen (*cep*) sind  $3\frac{1}{2}$ —9 mm lang,  $3\frac{1}{2}$ —10 mm hoch und 3—11 mm breit. Die Keilbeinhöhle (*ss*) ist 7 mm breit,  $4\frac{1}{2}$  mm hoch und  $3\frac{1}{2}$  mm lang, sie mündet mit einer  $1\frac{1}{2}$  mm weiten Öffnung (*os*), dem ostium sphenoidale.

## Planche 81.

Grandeur nature. — Enfant de 3 ans  $\frac{1}{2}$ .

*rf* recessus frontal, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *hs* hiatus semilunaire, *pu* processus uncinatus, *os* ostium du sinus sphénoïdal, *ss* sinus sphénoïdal, *cm* cornet moyen, *mm* méat moyen, *mns* méat supérieur.

Coupe sagittale d'une tête de 3 ans  $\frac{1}{2}$  montrant le recessus frontal (*rf*) haut de 7 millim., long de 5 millim. et large de 4 millim., dont la large partie inférieure se trouve au-devant de l'hiatus semilunaire (*hs*) limité par le processus uncinatus (*pu*) et les cellules ethmoïdales antérieures. Sur la coupe on peut voir les différentes dimensions de chaque cellule ethmoïdale, le petit sinus sphénoïdal (*ss*), le cornet moyen (*cm*), les méats moyen (*mm*) et supérieur (*mns*). Les cellules ethmoïdales antérieures (*cea*) ont de 5 à 11 millim. de haut, de  $3\frac{1}{2}$  à 7 millim. de large et de 3 à 6 millim. de long. Les cellules ethmoïdales postérieures (*cep*) ont de  $3\frac{1}{2}$  à 9 millim. de long, de  $3\frac{1}{2}$  à 10 millim. de haut et de 3 à 11 millim. de large. Le sinus sphénoïdal (*ss*) a 7 millim. de large,  $4\frac{1}{2}$  millim. de haut et  $3\frac{1}{2}$  millim. de long, il s'ouvre par un ostium large de  $1\frac{1}{2}$  millim. (*os*).

## Plate 81.

Natural size. — Child of  $3\frac{1}{2}$  years.

*rf* frontal recess, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *hs* semilunar hiatus, *pu* uncinate process, *os* sphenoidal ostium, *ss* sphenoidal sinus, *cm* middle concha, *mm* middle meatus, *mns* upper meatus.

Longitudinal vertical section through the head of a child aged  $3\frac{1}{2}$  years, shewing the frontal recess (*rf*), which is 7 mm high, 5 mm long and 4 mm wide. Its wider inferior portion lies in front the semilunar hiatus (*hs*) and is enclosed between the uncinate process (*pu*) and the anterior ethmoidal cells (*cea*). The section illustrates the variations in size of the individual ethmoidal cells, the small sphenoidal sinus (*ss*), the middle concha (*cm*) and the middle (*mm*) and upper (*mns*) meatus. The anterior ethmoidal cells (*cea*) are 5 to 11 mm high,  $3\frac{1}{2}$  to 7 mm wide and 3 to 6 mm long. The posterior ethmoidal cells (*cep*) are  $3\frac{1}{2}$  to 9 mm long,  $3\frac{1}{2}$  to 10 mm high and 3 to 11 mm wide. The sphenoidal sinus (*ss*) is 7 mm wide,  $4\frac{1}{2}$  mm high and  $3\frac{1}{2}$  mm long. Its opening, the sphenoidal ostium (*os*), is  $1\frac{1}{2}$  mm wide.

*sf* sinus frontalis, *of* ostium frontale, *hs* hiatus semilunaris, *pu* processus uncinatus, *cea* cellula ethmoidalis anterior, *sl* saccus lacrimalis.

Der Sagittalschnitt eines 6 Jahre alten Kopfes zeigt die Stirnhöhle (*sf*), die vorderen Siebbeinzellen (*cea*), einen Teil des Tränensackes (*sl*), den hiatus semilunaris (*hs*) und den processus uncinatus (*pu*). Die linke Stirnhöhle (*sf*) ist 13 mm lang, 18 mm hoch und 12 mm breit, ihre Mündung (*of*) liegt am vordersten Ende des hiatus semilunaris (*hs*), welche der processus uncinatus (*pu*) begrenzt. Vor dem untersten Teile der Stirnhöhle (*sf*) ist ein Teil des Tränensackes (*sl*) zu sehen. Die vorderen Siebbeinzellen zeigen eine Ausbreitung von 8—11 mm Höhe, 5—6 mm Länge und 6 mm Breite.

## Planche 82.

Grandeur nature. — Enfant de 6 ans.

*sf* sinus frontal, *of* ostium du sinus frontal, *hs* hiatus semilunaire, *pu* processus uncinatus, *cea* cellule ethmoïdale antérieure, *sl* sac lacrymal.

Coupe sagittale d'une tête de 6 ans montrant le sinus frontal (*sf*) les cellules ethmoïdales antérieures (*cea*), une partie du sac lacrymal (*sl*), l'hiatus semilunaire (*hs*) et le processus uncinatus (*pu*). Le sinus frontal gauche (*sf*) est long de 13 millim., haut de 18 millim., large de 12 millim. Son ouverture (*of*) se trouve dans la partie antérieure de l'hiatus semilunaire (*hs*) limitée par le processus uncinatus (*pu*). Au-dessous du sinus frontal (*sf*) on voit une partie du sac lacrymal (*sl*). Les cellules ethmoïdales antérieures ont une hauteur qui varie entre 8 et 11 millim., une longueur de 5 à 6 millim. et une largeur de 6 millim.

## Plate 82.

Natural size. — Child of 6 years.

*sf* frontal sinus, *of* frontal ostium, *hs* semilunar hiatus, *pu* uncinat process, *cea* anterior ethmoidal cell, *sl* lachrymal sac.

Longitudinal vertical section through the skull of a child aged 6 years, shewing the frontal sinus (*sf*), the anterior ethmoidal cells (*cea*), part of the lachrymal sac (*sl*), the semilunar hiatus (*hs*) and the uncinat process (*pu*). The left frontal sinus (*sf*) is 13 mm long, 18 mm high, and 12 mm wide. Its orifice (*of*) opens into the anterior end of the semilunar hiatus (*hs*), which is bordered by the uncinat process (*pu*). In front of the lower portion of the frontal sinus (*sf*) part of the lachrymal sac (*sl*) is visible. The anterior ethmoidal cells measure 8 to 11 mm in height, 5 to 6 mm in length and 6 mm in width.

*sf* sinus frontalis, *of* ostium frontale, *cei* cellula ethmoidalis anterior, *hs* hiatus semilunaris, *pu* processus uncinatus, *mnm* meatus narium medius, *cm* concha media.

Der Sagittalschnitt eines 6 Jahre alten Kopfes stellt den korrespondierenden Schnitt der Tafel 82 dar. Das Bild zeigt die längliche ovale Mündung (*of*) der linken Stirnhöhle, welche direkt in den hiatus semilunaris (*hs*) übergeht. Der vorderste Teil der mittleren Nasenmuschel (*cm*) und des mittleren Nasenganges (*mnm*) und das von der Nasenhöhle aus bedeckte Mündungsgebiet der Stirnhöhle (*of*, *hs*, *pu*) ist gut zu übersehen. Die Maasse der Stirnhöhle und der vorderen Siebbeinzellen sind in der Tafel 82 angegeben.

## Planche 83.

Grandeur nature. — Enfant de 6 ans.

*sf* sinus frontal, *of* ostium du sinus frontal, *cei* cellule ethmoïdale antérieure, *hs* hiatus semilunaire, *pu* processus uncinatus, *mnm* méat moyen, *cm* cornet moyen.

Coupe sagittale de la tête d'un enfant de 6 ans correspondant à la coupe représentée sur la planche 82. La figure représente l'ouverture ovulaire allongée du sinus frontal gauche (*of*) qui se continue directement dans l'hiatus semilunaire (*hs*). On voit très distinctement la partie antérieure du cornet moyen (*cm*) et du méat moyen (*mnm*) et toute la région autour de l'ouverture du sinus frontal (*of*, *hs*, *pu*). Les mesures du sinus frontal et des cellules ethmoïdales antérieures sont indiquées sur la planche 82.

## Plate 83.

Natural size. — Child of 6 years.

*sf* frontal sinus, *of* frontal ostium, *cei* anterior ethmoidal cell, *hs* semilunar hiatus, *pu* uncinate process, *mnm* middle meatus, *cm* middle concha.

Longitudinal vertical section through the head of a child aged 6 years, shewing the section corresponding to that illustrated in Plate 82. The elongated oval opening (*of*) of the left frontal sinus is seen merging into the semilunar hiatus (*hs*). A good view is obtained of the middle concha (*cm*), the middle meatus (*mnm*), and the region of the frontal ostium (*of*, *hs*, *pu*) which would otherwise be hidden by the lateral wall of the nasal fossa. The measurements of the frontal sinus and anterior ethmoidal cells are given in the description of Plate 82.

*sf* sinus frontalis, *of* ostium frontale, *cea* cellula ethmoidalis anterior, *pu* processus uncinatus, *hs* hiatus semilunaris, *ci* concha inferior, *mni* meatus narium inferior.

Der Sagittalschnitt des 6 Jahre alten Kopfes zeigt die Stirnhöhle (*sf*), die Mündung der Stirnhöhle (*of*), die vorderen Siebbeinzellen (*cea*), den hiatus semilunaris (*hs*) und den processus uncinatus (*pu*). Die rechte Stirnhöhle (*sf*) ist 17 mm hoch, 10 mm lang und 11 mm breit. Die Mündung der Stirnhöhle (*of*) fliesst direkt mit dem hiatus semilunaris (*hs*) zusammen. Die vorderen Siebbeinzellen (*cea*) zeigen eine Ausdehnung von 10—13 mm Höhe, 5—6 mm Länge und 7 mm Breite.

## Planche 84.

Grandeur nature. — Enfant de 6 ans.

*sf* sinus frontal, *of* ostium du sinus frontal, *cea* cellule ethmoïdale antérieure, *pu* processus uncinatus, *hs* hiatus semilunaire, *ci* cornet inférieur, *mni* méat inférieur.

Coupe sagittale d'une tête de 6 ans présente le sinus frontal (*sf*) et son ouverture (*of*), les cellules ethmoïdales antérieures (*cea*), l'hiatus semilunaire (*hs*) et le processus uncinatus (*pu*). Le sinus frontal droit (*sf*) est haut de 17 millim., long de 10 millim., large de 11 millim. L'ouverture du sinus frontal (*of*) se continue directement avec l'hiatus semilunaire. Les cellules ethmoïdales antérieures (*cea*) ont les dimensions suivantes: hauteur 10 à 13 millim., longueur 5 à 6 millim., largeur 7 millim.

## Plate 84.

Natural size. — Child of 6 years.

*sf* frontal sinus, *of* frontal ostium, *cea* anterior ethmoidal cell, *pu* uncinate process, *hs* semilunar hiatus, *ci* lower concha, *mni* lower meatus.

Longitudinal vertical section through the head of a child aged 6 years, shewing the frontal sinus (*sf*), the orifice of the frontal sinus (*of*), the anterior ethmoidal cells (*cea*), the semilunar hiatus (*hs*) and the uncinate process (*pu*). The right frontal sinus (*sf*) is 17 mm high, 10 mm long and 11 mm wide. The outlet of the frontal sinus (*of*) merges uninterruptedly into the semilunar hiatus (*hs*). The anterior ethmoidal cells (*cea*) measure 10 to 13 mm in height, 5 to 6 mm in length and 7 mm in width.

## Tafel 85.

Natürliche Grösse. — 6 Jahre altes Kind.

*sf* sinus frontalis, *of* ostium frontale, *hs* hiatus semilunaris, *pu* processus uncinatus, *cea* cellula, ethmoidalis anterior.

Der Sagittalschnitt eines 6 Jahre alten Kopfes stellt den korrespondierenden Schnitt der Tafel 84 dar. Das Bild zeigt die rechte Stirnhöhle (*sf*) und die benachbarten vorderen Siebbeinzellen (*cea*). Die Mündung der Stirnhöhle (*of*) ist gut zu übersehen, sie übergeht direkt in den hiatus semilunaris (*hs*), welchen der processus uncinatus (*pu*) begrenzt. Die Maasse der Stirnhöhle und der vorderen Siebbeinzellen sind in der Tafel 84 angegeben.

## Planche 85.

Grandeur nature. — Enfant de 6 ans.

*sf* sinus frontal, *of* ostium du sinus frontal, *hs* hiatus semilunaire, *pu* processus uncinatus, *cea* cellule ethmoïdale antérieure.

Coupe sagittale d'une tête de 6 ans représentant la coupe correspondant à la planche 84. La figure montre le sinus frontal droit (*sf*) et les cellules ethmoïdales antérieures avoisinantes (*cea*). L'orifice du sinus frontal (*of*) est bien visible et se continue directement avec l'hiatus semilunaire, (*hs*) limité par le processus uncinatus (*pu*). Les mesures du sinus frontal et des cellules ethmoïdales antérieures sont indiquées sur la planche 84.

## Plate 85.

Natural size. — Child of 6 years.

*sf* frontal sinus, *of* frontal ostium, *hs* semilunar hiatus, *pu* uncinate process, *cea* anterior ethmoidal cell.

Longitudinal vertical section through the head of a child aged 6 years, shewing the section corresponding to that illustrated in Plate 84. The right frontal sinus (*sf*) and the adjoining anterior ethmoidal cells (*cea*) are shewn. The opening of the frontal sinus (*of*) is clearly visible. It merges into the semilunar hiatus (*hs*) which is bordered by the uncinate process (*pu*). The measurements of the frontal sinus and anterior ethmoidal cells are given in the description of Plate 84.

## Tafel 88.

Natürliche Grösse. —  $7\frac{1}{2}$  Jahre altes Kind.

*sf* sinus frontalis, *pu* processus uncinatus, *be* bulla ethmoidalis, *hs* hiatus semilunaris, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *ss* sinus sphenoidalis, *rse* recessus sphenothmoidalis, *ci* concha inferior, *mni* meatus narium inferior, *cm* concha media, *mns* meatus narium superior, *cs* concha superior.

Der Sagittalschnitt eines  $7\frac{1}{2}$  Jahre alten Kopfes illustriert die gut ausgebildeten Nebenhöhlen. Die rechte Stirnhöhle (*sf*) ist 17 mm hoch, 11 mm lang und 7 mm breit, ihre Mündung fliesst mit dem obersten vordersten Teil des hiatus semilunaris (*hs*) zusammen, welcher vom processus uncinatus (*pu*) und von der bulla ethmoidalis (*be*) begrenzt, mit einer kuppelförmigen Erweiterung in der Stirnhöhle (*sf*) zu enden scheint. Durch die Entfernung der mittleren Nasenmuschel (*cm*) ist das erwähnte Gebiet gut zu übersehen. Die vordere Siebbeinzelle (*cea*) ist 13 mm hoch, 7 mm breit und 5 mm lang. Die hintere Siebbeinzelle (*cep*) ist 17 mm lang, 10 mm hoch und 9 mm breit, sie mündet mit einer länglich ovalen Öffnung in den oberen Nasengang (*mns*). Die Keilbeinhöhle (*ss*) ist 12 mm lang, 13 mm hoch und 9 mm breit, das ostium sphenoidale mündet mit einer 2 mm weiten runden Öffnung in den recessus sphenothmoidalis.

## Planche 88.

Grandeur nature. — Enfant de 7 ans  $\frac{1}{2}$ .

*sf* sinus frontal, *pu* processus uncinatus, *be* bulle ethmoïdale, *hs* hiatus semilunaire, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *ss* sinus sphénoïdal, *rse* recessus sphénoethmoïdal, *ci* cornet inférieur, *mni* méat inférieur, *cm* cornet moyen, *mns* méat supérieur, *cs* cornet supérieur.

Coupe sagittale d'une tête de 7 ans  $\frac{1}{2}$  montrant les sinus bien développés. Le sinus frontal droit (*sf*) est haut de 17 millim., long de 11 millim., large de 7 millim. Son ouverture se confond avec la partie antérieure de l'hiatus semilunaire (*hs*), limitée par le processus uncinatus (*pu*) et la bulle ethmoïdale (*be*), et paraissant se terminer par une dilatation eupuliforme dans le sinus frontal (*sf*). On voit très bien cette région par suite de la section du cornet moyen (*cm*). La cellule ethmoïdale antérieure (*cea*) a une hauteur de 13 millim., une largeur de 7 millim. et une longueur de 5 millim. La cellule ethmoïdale postérieure (*cep*) est longue de 17 millim., haute de 10 millim. et large de 9 millim. Elle se termine par une ouverture ovulaire allongée dans le méat supérieur (*mns*). Le sinus sphénoïdal (*ss*) a 12 millim. de longueur, 13 de hauteur et 9 de largeur. L'ostium sphénoïdal est large de 2 millim. et donne dans le recessus sphénoethmoïdal.

## Plate 88.

Natural size. — Child of  $7\frac{1}{2}$  years.

*sf* frontal sinus, *pu* uncinate process, *be* ethmoidal bulla, *hs* semilunar hiatus, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *ss* sphenoidal sinus, *rse* sphenothmoidal recess, *ci* lower concha, *mni* lower meatus, *cm* middle concha, *mns* upper meatus, *cs* upper concha.

Longitudinal vertical section through the head of a child aged  $7\frac{1}{2}$  years, shewing the well developed sinuses. The right frontal sinus (*sf*) is 17 mm high, 11 mm long and 7 mm wide. Its aperture merges into the upper anterior portion of the semilunar hiatus (*hs*), which is enclosed between the uncinate process (*pu*) and the ethmoidal bulla (*be*) and appears to terminate at the frontal sinus (*sf*) in a dome-shaped enlargement. In consequence of the removal of the middle concha (*cm*) this region has been rendered well visible. The anterior ethmoidal cell (*cea*) is 13 mm high, 7 mm wide and 5 mm long. The posterior ethmoidal cell (*cep*) is 17 mm long, 10 mm high and 9 mm wide; it communicates with the upper meatus (*mns*) by an elongated oval orifice. The sphenoidal sinus (*ss*) is 12 mm long, 13 mm high, and 9 mm wide; the sphenoidal ostium opens into the sphenothmoidal recess by a circular aperture, 2 mm wide.

## Tafel 89.

Natürliche Grösse. —  $7\frac{1}{2}$  Jahre altes Kind.

*sf* sinus frontalis, *of* ostium frontale, *hs* hiatus semilunaris, *pu* processus uncinatus, *be* bulla ethmoidalis, *sm* sinus maxillaris, *cea* cellula ethmoidalis anterior, *ci* concha inferior, *mni* meatus narium inferior, *cm* concha media.

Der Frontalschnitt eines  $7\frac{1}{2}$  Jahre alten Kopfes ist etwas schräg geführt und zeigt das Mündungsgebiet der Stirnhöhle (*sf*) und der vorderen Siebbeinzellen (*cea*), den hiatus semilunaris (*hs*), welchen der processus uncinatus (*pu*) und die bulla ethmoidalis (*be*) begrenzt. Oberhalb der bulla ethmoidalis (*be*), im recessus bullaris ist die ovale Öffnung einer vorderen Siebbeinzelle (*cea*) zu sehen. Die Stirnhöhle (*sf*) ist 14 mm hoch, 9 mm breit und 4 mm lang, sie mündet mit einer länglich ovalen Öffnung (*of*) knapp am vordersten Ende des hiatus semilunaris (*hs*). Unterhalb der Stirnhöhlenmündung (*of*) und vor dem vorderen Ende des hiatus semilunaris (*hs*) ist die ovale Öffnung einer vorderen Siebbeinzelle (*cea*) zu sehen; dieselbe ist 11 mm lang, 8 mm hoch und 7 mm breit. Im Bereiche des unteren Nasenganges (*mni*) ist der vordere Teil der Kieferhöhle (*sm*) zu übersehen.

## Planche 89.

Grandeur nature. — Enfant de 7 ans  $\frac{1}{2}$ .

*sf* sinus frontal, *of* ostium du sinus frontal, *hs* hiatus semilunaire, *pu* processus uncinatus, *be* bulle ethmoïdale, *sm* sinus maxillaire, *cea* cellule ethmoïdale antérieure, *ci* cornet inférieur, *mni* méat inférieur, *cm* cornet moyen.

La coupe frontale de la tête d'un enfant de 7 ans  $\frac{1}{2}$  est légèrement oblique et montre la région autour de l'ouverture du sinus frontal (*sf*) et des cellules ethmoïdales antérieures (*cea*), l'hiatus semilunaire (*hs*) limité par le processus uncinatus (*pu*) et la bulle ethmoïdale (*be*). Au dessus de la bulle ethmoïdale (*be*) dans le recessus bullaire on peut voir l'ouverture ovale d'une cellule ethmoïdale antérieure (*cea*). Le sinus frontal (*sf*) a une hauteur de 14 millim., une largeur de 9 millim. et une longueur de 4 millim. Il se termine par une ouverture (*of*) ovulaire allongée juste à la partie antérieure de l'hiatus semilunaire (*hs*). Au-dessous de l'ostium du sinus frontal (*of*) et devant la partie antérieure de l'hiatus semilunaire (*hs*) on peut voir l'ouverture ovale d'une cellule ethmoïdale antérieure (*cea*); celle-ci est longue de 11 millim. haute de 8 millim. et large de 7 millim. Au niveau du méat inférieur (*mni*) on voit la partie antérieure du sinus maxillaire (*sm*).

## Plate 89.

Natural size. — Child of  $7\frac{1}{2}$  years.

*sf* frontal sinus, *of* frontal ostium, *hs* semilunar hiatus, *pu* uncinate process, *be* ethmoidal bulla, *sm* maxillary antrum, *cea* anterior ethmoidal cell, *ci* lower concha, *mni* lower meatus, *cm* middle concha.

Section through the head of a child of  $7\frac{1}{2}$  years, cut in a transverse but slightly oblique direction, so as to shew the region of the orifices of the frontal sinus (*sf*) and anterior ethmoidal cells (*cea*), the semilunar hiatus, which is enclosed between the uncinate process (*pu*) and the ethmoidal bulla (*be*). Above the ethmoidal bulla (*be*), in the bullar recess, is the oval aperture of an anterior ethmoidal cell (*cea*). The frontal sinus (*sf*) is 14 mm high, 9 mm wide, and 4 mm long; it opens by an elongated oval aperture (*of*) close to the anterior extremity of the semilunar hiatus (*hs*). Below the frontal ostium (*of*) and in front of the anterior extremity of the semilunar hiatus (*hs*) the oval orifice of an anterior ethmoidal cell (*cea*) is visible. This cell is 11 mm long, 8 mm high and 7 mm wide. Close to the lower meatus (*mni*) the anterior portion of the maxillary antrum (*sm*) is shewn.

Natürliche Grösse. — 7½ Jahre altes Kind.

*sm* sinus maxillaris, *cea* cellula ethmoidalis anterior, *cep* cellula ethmoidalis posterior, *os* ostium sphenoidale, *ci* concha inferior, *mni* meatus narium inferior, *cm* concha media, *mn* meatus narium medius, *cs* concha superior, *mns* meatus narium superior.

Der Frontalschnitt eines 7½ Jahre alten Kopfes zeigt die Kieferhöhle (*sm*), die Siebbeinzellen (*cea* und *cep*), die untere (*ci*), mittlere (*cm*) und obere (*cs*) Nasenmuschel, den unteren (*mni*), mittleren (*mn*) und oberen (*mns*) Nasengang und die Mündung der Keilbeinhöhle (*os*). Die Kieferhöhle (*sm*) ist im Bereiche des unteren (*mni*) und des mittleren (*mn*) Nasenganges zu übersehen, sie ist 38 mm lang, 23 mm hoch und 20 mm breit. Die oberhalb des oberen Nasenganges (*mns*) liegende hintere Siebbeinzelle (*cep*) ist 11 mm lang, 10 mm hoch und 6 mm breit. Die linke Keilbeinhöhle ist 12 mm hoch, 11 mm breit und 8 mm lang; sie mündet unterhalb des Nasendaches mit einer 4 mm länglich ovalen Öffnung (*os*).

## Planche 90.

Grandeur nature. — Enfant de 7 ans ½.

*sm* sinus maxillaire, *cea* cellule ethmoïdale antérieure, *cep* cellule ethmoïdale postérieure, *os* ostium du sinus sphénoïdal, *ci* cornet inférieur, *mni* méat inférieur, *cm* cornet moyen, *mn* méat moyen, *cs* cornet supérieur, *mns* méat supérieur.

La coupe frontale de la tête d'un enfant de 7 ans ½ montre le sinus maxillaire (*sm*), les cellules ethmoïdales (*cea* et *cep*), les cornets inférieur (*ci*), moyen (*cm*), supérieur (*cs*), les méats inférieur (*mni*) moyen (*mn*) et supérieur (*mns*) et l'ostium du sinus sphénoïdal (*os*). On peut voir le sinus maxillaire (*sm*) au niveau des méats inférieur (*mni*) et moyen (*mn*), il est long de 38 millim., haut de 23 millim. et large de 20 millim. La cellule ethmoïdale postérieure (*cep*), située au-dessus du méat supérieur, est longue de 11 millim., haute de 10 millim. et large de 6 millim. Le sinus sphénoïdal gauche est haut de 12 millim., large de 11 millim. et long de 8 millim. Il se termine sous le toit de la fosse nasale par une ouverture ovale de 4 millim. de longueur (*os*).

## Plate 90.

Natural size. — Child of 7½ years.

*sm* maxillary antrum, *cea* anterior ethmoidal cell, *cep* posterior ethmoidal cell, *os* sphenoidal ostium, *ci* lower concha, *mni* lower meatus, *cm* middle concha, *mn* middle meatus, *cs* upper concha, *mns* upper meatus.

Coronal section through the head of a child aged 7½ years, shewing the maxillary antrum (*sm*), the ethmoidal cells (*cea* and *cep*), the lower (*ci*), middle (*cm*) and upper (*cs*) concha, the lower (*mni*), middle (*mn*) and upper (*mns*) meatus, and the ostium of the sphenoidal sinus (*os*). The maxillary antrum (*sm*) can be seen in its relations with the lower (*mni*) and middle (*mn*) meatus. It is 38 mm long, 23 mm high and 20 mm wide. The posterior ethmoidal cell (*cep*) situated above the upper meatus (*mns*) is 11 mm long, 10 mm high and 6 mm wide. The left sphenoidal sinus is 12 mm high, 11 mm wide and 8 mm long; its outlet, an elongated oval opening (*os*), 4 mm wide, lies underneath the roof of the nasal fossa.

Natürliche Grösse. — Schädel eines 13 jähr. Kindes.

*sfd* sinus frontalis dexter, *sfs* sinus frontalis sinister.

Die Figur zeigt die Röntgenaufnahme eines 13 jähr. Kinderschädels. Die rechte Stirnhöhle (*sfd*) hat eine Ausbreitung in vertikaler Richtung von 14 mm und in horizontaler Richtung von 20 mm. Die linke Stirnhöhle (*sfs*) hat eine Ausdehnung in vertikaler Richtung von 14 mm und in horizontaler Richtung von 22 mm.

## Planche 95.

Grandeur nature. — Crâne d'un enfant de 13 ans.

*sfd* sinus frontal droit, *sfs* sinus frontal gauche.

Figure montrant le radiogramme d'un crâne d'un enfant de 13 ans. Le sinus frontal droit (*sfd*) a une étendue de 14 millim. dans la direction verticale et de 20 millim. dans la direction horizontale. Le sinus frontal gauche (*sfs*) a une étendue de 14 millim. dans la direction verticale et de 22 millim. dans la direction horizontale.

## Plate 95.

Natural size. — Skull of child 13 years old.

*sfd* right frontal sinus, *sfs* left frontal sinus.

The figure shews a skiagram of a skull of child 13 years old. The right frontal sinus (*sfd*) measures 14 mm in the vertical and 20 mm in the horizontal direction. The left frontal sinus (*sfs*) measures 14 mm in the vertical and 22 mm in the horizontal direction.

Natürliche Grösse. — Schädel eines 13jähr. Kindes.

*sfd* sinus frontalis dexter, *sfs* sinus frontalis sinister.

Die Figur zeigt die Röntgenaufnahme eines 13jähr. Kinderschädels. Die rechte Stirnhöhle (*sfd*) hat eine Ausbreitung in der vertikalen Richtung von 13 mm und in der horizontalen Richtung von 17 mm. Die linke Stirnhöhle (*sfs*) hat eine Ausdehnung in der vertikalen Richtung von 12 mm und in der horizontalen Richtung von 18 mm.

## Planche 96.

Grandeur nature. — Crâne d'un enfant de 13 ans.

*sfd* sinus frontal droit, *sfs* sinus frontal gauche.

Figure montrant le radiogramme d'un crâne d'un enfant de 13 ans. Le sinus frontal droit (*sfd*) a une étendue de 13 millim. dans la direction verticale et de 17 millim. dans la direction horizontale. Le sinus frontal gauche (*sfs*) a une étendue de 12 millim. dans la direction verticale et de 18 millim. dans la direction horizontale.

## Plate 96.

Natural size. — Skull of child 13 years old.

*sfd* right frontal sinus, *sfs* left frontal sinus.

The figure shews a skiagram of a skull of child 13 years old. The right frontal sinus (*sfd*) measures 13 mm in the vertical and 17 mm in the horizontal direction. The left frontal sinus (*sfs*) measures 12 mm in the vertical and 18 mm in the horizontal direction.

Natürliche Grösse. — Schädel eines 14 jähr. Kindes.

*sfs* sinus frontalis sinister.

Die Figur illustriert die Röntgenaufnahme der Stirnhöhlen eines 14 Jahre alten Kinderschädels. Auf der rechten Seite fehlt die Stirnhöhle, auf der linken Seite zeigt die linke Stirnhöhle (*s/s*) eine Ausdehnung von 10 mm im Schuppenteile des Stirnbeines.

## Planche 99.

Grandeur nature. — Crâne d'un enfant de 14 ans.

*sfs* sinus frontal gauche.

La figure montre le radiogramme d'un crâne d'un enfant de 14 ans. Le sinus frontal manque du côté droit. Du côté gauche, le sinus frontal (*s/s*) a une étendue de 10 millim. dans la squame de l'os frontal.

## Plate 99.

Natural size. — Skull of child 14 years old.

*sfs* left frontal sinus.

Skiagram shewing the frontal sinus of a skull 14 years old. The right frontal sinus is not developed, the left sinus (*s/s*) extends into the squamous part of the frontal bone for a distance of 10 mm.

*sfd* sinus frontalis dexter, *sfs* sinus frontalis sinister.

Die Figur zeigt die Röntgenaufnahme der Stirnhöhlen eines 15 Jahre alten Kinderschädels. Die rechte Stirnhöhle (*sfd*) hat eine Ausdehnung in der vertikalen Richtung von 5 mm und in der horizontalen Richtung von 5 mm. Die linke Stirnhöhle (*sfs*) hat eine Ausbreitung in der vertikalen Richtung von 11 mm und in der horizontalen Richtung von 8 mm.

## Planche 100.

Grandeur nature. — Crâne d'un enfant de 15 ans.

*sfd* sinus frontal droit, *sfs* sinus frontal gauche.

Figure montrant le radiogramme des sinus frontaux d'un crâne d'un enfant de 15 ans. Le sinus frontal droit (*sfd*) a une étendue de 5 millim. dans la direction verticale et de 5 millim. dans la direction horizontale. Le sinus frontal gauche (*sfs*) a une étendue de 11 millim dans la direction verticale et de 8 millim. dans la direction horizontale.

## Plate 100.

Natural size. — Skull of child 15 years old.

*sfd* right frontal sinus, *sfs* left frontal sinus.

Skiagram shewing the frontal sinuses in the skull of a child aged 15 years. The right frontal sinus (*sfd*) measures 5 mm in the vertical and 5 mm in the horizontal direction. The left frontal sinus (*sfs*) measures 11 mm in the vertical and 8 mm in the horizontal direction.
